

REMARKS

In view of the above amendments and the following remarks, reconsideration and further examination are respectfully requested.

I. Amendments to the Specification

The specification has been reviewed and revised to improve its English grammar. The amendments to the specification have been incorporated into a substitute specification. Attached are two versions of the substitute specification, a marked-up version showing the revisions, as well as a clean version. No new matter has been added.

II. Amendments to the Drawings

As mentioned above, proposed drawing amendments are submitted herewith under a separate cover letter. Specifically, Figures 13A and 13B have been amended to correct a typographical error by replacing the term “monotonously” with the term “monotonically.” No new matter has been added.

III. Telephone Interview

The Applicants would like to thank Examiner Leiby for granting and conducting a personal interview on May 13, 2010 in connection with the above-identified application.

During the interview the 35 U.S.C. § 112, first paragraph rejection of claims 14-20 was discussed. Specifically, the Examiner was informed that the Applicants agreed to cancel claims 18-20, which were directed to a non-elected embodiment of the invention. Additionally, the Examiner was informed that support for the limitations of claims 14-17 can be found, at least, in

paragraphs [0305]-[0307], [0344], [0345], [0369], and [0516] of the publication of the present application (a more detailed discussion of the support for the limitations of claims 14-17 is provided below in section V).

The Examiner essentially agreed that, in view of the above, the 35 U.S.C. § 112, first paragraph rejection would be overcome.

Next, the 35 U.S.C. § 102 rejection was discussed. Initially, the Examiner expressed a concern that claim 10 may not be consistent with figure 40 (i.e., the elected invention). Specifically, the Examiner was concerned that claim 10 is not consistent with the elected invention because figure 40 does not appear to illustrate the claimed spatial processing unit.

However, after reviewing the specification, the Applicants respectfully submit that claim 10 is supported by figure 40, since the specification indicates that the transformation portion 915 of the visual processing device 910 illustrated in figure 40 can perform the same function as the spacial processing portion 2 and the visual processing portion 3, as illustrated in Figure 7. As a result, the Applicants submit that claims 9 and 10 are in fact directed to the elected invention.

Next the 35 U.S.C. § 102 rejection of claim 11 was discussed. Specifically, the limitations of claim 11, regarding monotonically decreasing the value of the output signal with respect to the value of the processed signal, when the value of the image signal is fixed to a predetermined level, were discussed in view of the Hansen reference.

Specifically, during the interview the Applicants noted that the rejection of claim 11 equates the manual adjustment parameter 520 (see Fig. 9) of Hansen with the value of the input image signal being fixed to the predetermined level, as recited in claim 11. Then the Applicants explained that Hansen merely teaches that the manual adjustment parameter is essentially an upper limit of the brightness/contract that is manually set, such that, when the brightness/contrast

of the image is above the upper limit set according to the manual adjustment, then the brightness/contrast will automatically decrease until the brightness/contrast falls below the upper limit.

After the above-noted discussion of claim 11, the Examiner indicated that the phrase “when the value of the image signal is fixed to a predetermined level” was confusing and did not accurately describe the invention as illustrated in Figure 13A and as described in the specification. Additionally, the Examiner indicated that, if the limitations of claim 11 were incorporated into the independent claims and clarified to remove any ambiguities, then his rejection would most likely be overcome and he would be forced to update his search.

IV. Amendments to the Claims

Based on the above-mentioned telephone interview, independent claims 9, 10, 21 and 23-25 have been amended to include features similar to those previously recited in claim 11 and to clarify features of the invention recited therein and to further distinguish the present invention from the reference relied upon in the rejection discussed below.

In addition, claims 11, 13, 16 and 18-20 have been cancelled without prejudice or disclaimer of the subject matter contained therein.

It is also noted that claims 9, 10, 12, 14, 15, 17 and 21-25 have been amended to make a number of editorial revisions thereto. These editorial revisions have been made to place the claims in better U.S. form. Further, these editorial revisions have not been made to narrow the scope of protection of the claims, or to address issues related to patentability, and therefore, these amendments should not be construed as limiting the scope of equivalents of the claimed features offered by the Doctrine of Equivalents.

V. 35 U.S.C. § 112, First Paragraph Rejections

Claims 14-20 were rejected under 35 U.S.C. § 112, first paragraph, for failing to comply with the written description requirement. The rejection of claims 16 and 18-20 is considered moot based on their above-mentioned cancellation. Further, as discussed above in section III, this rejection is believed clearly inapplicable to claims 14, 15 and 17.

Claim 14 was rejected for reciting “the value of the output signal is convex upward with respect to the value of the image signal,” which was deemed by the Examiner as new matter. The Applicants respectfully submit that paragraphs [0344], [0345] and [0516] of the published application provide support for the above-mentioned limitation recited in claim 14.

Specifically, the Applicants note that paragraph [0516] discloses that “[i]n (1) through (7) above, each element of the first through seventh profile data was described as storing a value that has been calculated based on an equation M1 through M7.” Further, the Applicants note that paragraph [0344] states that “[t]he values C of the elements of the second profile data (the values of the output signal OS) are expressed by $C=F_4(A)*F_5(A/B)$ (hereinafter, this is referred to as Equation M2) using the value A of the input signal IS, the value B of the unsharp signal US, a dynamic range compression function F4, and an enhancement function F5.” Additionally, the Applicants note that paragraph [0345] discloses that “[h]ere, the dynamic range compression function F4 is for example a monotonously increasing function such as a concave power function. For example, it is expressed by $F_4(x)=x^{\gamma}(0<\gamma<1)$. The enhancement function F5 is a power function. It is for example expressed by $F_5(x)=x^{\alpha}(0<\alpha\leq 1)$.”

Thus, in view of the above, it is submitted that, in equation M2, when an image signal (A) and a processed signal are the same, the enhancement function F5 becomes “1,” and an output signal (C) becomes the value of convex upward according to the dynamic range

compression function F4. As a result, it is respectfully submitted that the phrase “the value of the output signal is convex upward with respect to the value of the image signal,” as recited in claim 14, is not new matter.

Claim 15 was rejected for reciting “a difference/ratio between the processed signal and the image signal,” which was deemed by the Examiner as new matter. The Applicants respectfully submit that paragraphs [0305]-[0307] of the published application provide support for the above-mentioned limitation recited in claim 15.

Specifically, paragraph [0307] states that “[t]he first profile data are determined in accordance with a computation that includes a function for enhancing the difference between the respective transformed values that are obtained by performing a predetermined transformation with respect to the input signal IS and the unsharp signal US. By doing this, it becomes possible to enhance the respective differences after transforming the input signal IS and the unsharp signal US in separate spaces. Thus, it is possible to achieve enhancement that is suited for the visual characteristics, for example” (emphasis added to underlined portion).

As a result, it is respectfully submitted that the phrase “a difference/ratio between the processed signal and the image signal,” as previously recited in claim 15, is not new matter.

Claim 17 was rejected for reciting “when the value of the image signal is fixed to a predetermined level,” which was deemed by the Examiner as new matter. The Applicants respectfully submit that paragraph [0369] of the published application provides support for the above-mentioned limitation recited in claim 17.

Specifically, the Applicants note that the phrase “when the value of the image signal is fixed to a predetermined level” is based on the description of γ and α , etc. of functions F4 and F5, in the equation M2 as described in the paragraph [0369]. Paragraph [0369] states that “[i]t

should be noted that if the power multiplier α of the enhancement function F5 shown in FIG. 18 is larger than 0.4, then it is possible to raise the visible contrast of the output signal OS over the input signal IS while performing compression of the dynamic range.”

In the above-noted context of equation M2 and functions F4 and F5, setting $\theta = \gamma + \alpha$, when θ is greater than 1, the equation M2 is $C = (A^\theta) / (B^{0.4})$ (x^y denotes x raised to the power of y). Therefore, in a local area near the target pixel, a value of B (a value of a processed signal, e.g., an average value of an image region with a predetermined size) is deemed constant. Thus, the value of C is in proportion to the value of the function (A^θ) , and the conversion characteristic according to the above-noted “proportion” is obtained. Further, since θ is greater than 1, the value of C becomes the value obtained by the downward convex function, as recited in claim 17.

Therefore, for the reasons discussed above, it is submitted that when the value of the processed signal US (B) is fixed to a predetermined level, the output signal OS (C) is downward convex with respect to the input signal IS (A), as required by claim 17.

As a result, it is respectfully submitted that the phrase “when the value of the image signal is fixed to a predetermined level,” as recited in claim 17, is not new matter.

VI. 35 U.S.C. § 102 Rejection

Claims 9-13 and 21-25 were rejected under 35 U.S.C. § 102(b) as being anticipated by Hansen. This rejection is believed clearly inapplicable to amended independent claims 9, 10, 21 and 23-25 for the following reasons.

Amended independent claim 9 recites a device including a visual processing unit operable to: (i) determine a conversion characteristic in accordance with information from a

plurality of pixels surrounding a target pixel of an input image signal; (ii) convert the target pixel in accordance with the determined conversion characteristic; and (iii) output an output signal generated by performing visual processing to the image signal. In addition, claim 9 recites that the conversion characteristic is determined, such that within a predetermined input range of the image signal, and with respect to a specific value of the image signal, a corresponding value of the output signal monotonically decreases as a corresponding value of a processed signal, obtained by processing the input image signal, increases.

Initially, the Applicants note that the present rejection indicates that “determining a conversion characteristic in accordance with information from a plurality of pixels surrounding a target pixel of an input image signal,” as now recited in claim 9 is similar to determining the length/conversion characteristic for an image signal in accordance with ambient light, in the one shot circuit 325, as disclosed in Fig. 4 of Hansen.

However, the Applicants note that claim 9 requires the visual processing unit to determine the conversion characteristic for converting a level of the target pixel in accordance with the information from the plurality of pixels surrounding the target pixel, which is completely different than determining the conversion characteristic in accordance with the ambient light, as suggested by Hansen. As a result and for this above-noted reason alone, it is respectfully submitted that independent claim 9 is not anticipated by Hansen.

Regarding the above-mentioned distinctions between claim 9 and Hansen, the Applicants note that pages 4 and 5 of the Office Action state that the features of claim 9 are disclosed by Hansen as follows: (1) as shown figure 4 of Hansen, one shot circuit 325 determines a conversion characteristic of an image signal in accordance with the ambient light as shown in figure 9; (2) a brightness voltage signal is generated by the comparison circuit whose output is

connected to the brightness control circuit; and (3) the brightness control circuit controls the brightness (of the FED display) by changing a length of on-time duration based on the rows (the rows on the FED display) selected by the PWM enable signal, or by changing the display data by the column data.

In particular, the rejection indicates that “selecting the rows or columns whose brightness is to be changed” as disclosed by Hansen is equivalent to selecting the target pixel and the surrounding pixels of the target pixel.

However, after studying the Hansen reference, the Applicants note that Hansen’s technique aims to change the brightness of the display panel itself in accordance with the ambient light without deteriorating the resolution of grayscale (horizontal resolution). To achieve this, Hansen changes the voltage applied to the rows by a PWM signal. More specifically, Hansen teaches controlling the brightness of display panel to adjust the voltage applied to the rows by changing the length of an on-time window, such that the amplitude of the relative column voltage is kept constant so as not to deteriorate the resolution of grayscale (horizontal resolution) (see col. 7, lines 27-46).

In other words, Hansen teaches changing a brightness of the display itself without deteriorating the resolution of grayscale (horizontal resolution), by only changing the driving voltage applied to the rows in accordance with changes of ambient light without changing the driving voltage applied to the column.

Thus, in view of the above, it is clear that the above-noted disclosure of Hansen is not a disclosure of determining a conversion characteristic in accordance with information from a plurality of pixels surrounding a target pixel of an input image signal and converting the target pixel in accordance with the determined conversion characteristic, as required by claim 9.

Additionally, the Applicants would like to emphasize that claim 9 recites that the conversion characteristic is determined, such that within a predetermined input range of the image signal and with respect to a specific value of the image signal, a corresponding value of the output signal monotonically decreases as a corresponding value of a processed signal, obtained by processing the input image signal, increases.

As agreed upon during the above-mentioned telephone interview, Hanson merely discloses that the manual adjustment parameter is essentially an upper limit of the brightness/contrast that is manually set, such that, when the brightness/contrast of the image is above the upper limit set according to the manual adjustment, then the brightness/contrast will automatically decrease until the brightness/contrast falls below the upper limit, but fails to disclose or suggest that the conversion characteristic is determined, such that within a predetermined input range of the image signal and with respect to a specific value of the image signal, a corresponding value of the output signal monotonically decreases as a corresponding value of a processed signal, obtained by processing the input image signal, increases, as now recited in claim 9.

Therefore, because of the above-mentioned distinctions it is believed clear that independent claim 9 is not anticipated by Hansen.

As a result of the above-noted limitation recited in claim 9, the invention of claim 9 naturally improves image quality based on a brightness contrast related to human visual characteristics (i.e., humans perceive objects to be brighter in the center, the darker the surroundings, such that the brightness of the target image area is affected by the brightness of the wide surrounding image area of the target image area).

For example, when the average value of the pixel values of the wide surrounding image area is large (the level of the processed signal is large), that is, when it is bright, the present invention lowers the brightness of the target image area (lowers the level of the output signal). In contrast, when the average value of the pixel values of the wide surrounding image area is small (the level of the processed signal is small), that is, when it is dark, the present invention raises the brightness of the target image area (raises the level of the output signal). Thus, it is possible to improve image quality in a dark area which is large and dark when the image is captured in a backlit scene, and it is possible to prevent a bright region (such as the blue sky region) from losing its tones in the image including the wide and bright area (see, for example, line 26 on page 42 to line 14 on page 43 of the originally filed application).

In light of the discussion above, Hansen does not provide the above-mentioned benefits of the features recited by claim 9, because Hansen merely teaches (1) controlling the brightness of display panel to adjust the voltage applied to the rows by changing the length of an on-time window, such that the amplitude of the relative column voltage is kept constant so as not to deteriorate the resolution of grayscale, and (2) that the manual adjustment parameter is essentially an upper limit of the brightness/contrast that is manually set, such that, when the brightness/contrast of the image is above the upper limit set according to the manual adjustment, then the brightness/contrast will automatically decrease until the brightness/contrast falls below the upper limit.

Furthermore, there is no disclosure or suggestion in Hansen or elsewhere in the prior art of record which would have caused a person of ordinary skill in the art to modify Hansen to obtain the invention of independent claim 9. Accordingly, it is respectfully submitted that independent claim 9 is clearly allowable over the prior art of record.

Amended independent claims 10, 21, 23, 24 and 25 are directed to a device, a device, a method, a processor and a program, respectively and each recite features that correspond to the above-mentioned distinguishing features of independent claim 9. Thus, for the same reasons discussed above, it is respectfully submitted that independent claims 10, 21, 23, 24 and 25 and claims 12, 14, 15, 17 and 22 that depend therefrom are allowable over Hansen.

VII. Conclusion

In view of the above amendments and remarks, it is submitted that the present application is now in condition for allowance and an early notification thereof is earnestly requested. The Examiner is invited to contact the undersigned by telephone to resolve any remaining issues.

Respectfully submitted,

Haruo YAMASHITA et al.

DESCRIPTION

VISUAL PROCESSING DEVICE, VISUAL PROCESSING METHOD, VISUAL PROCESSING PROGRAM, AND SEMICONDUCTOR DEVICE

5

Background of the Invention

Technical Field

The present invention relates to visual processing devices, in
10 particular to visual processing devices that perform visual processing
such as spatial processing or gradation processing of an image signal.

Background Art

Spatial processing and gradation processing are known as
15 techniques for visually processing image signals of an original image.

Spatial processing involves using the pixels around a pixel to be
filtered when processing that pixel. Further, the technique of using an
image signal that has been subjected to spatial processing to perform
contrast enhancement or dynamic range (DR) compression, for example,
20 of an original image is known. With contrast enhancement, the
difference between the original image and the blur signal (the sharp
component of the image) is added to the original image, sharpening the
image. With DR compression, a portion of the blur signal is subtracted
from the original image, compressing the dynamic range.

25 Gradation processing is processing in which a lookup table (LUT)
is used to transform a pixel value for each pixel being processed without
regard for the pixels around the pixel being processed, and is also
referred to as "gamma correction." For example, in the case of contrast
enhancement, transformation of the pixel value is performed using a

LUT that produces a gradation of gray levels that appear frequently (whose area is large) in the original image. Well-known examples of gradation processing using a LUT include gradation processing in which a single LUT is chosen and used for the entire original image (histogram equalization) and gradation processing in which the original image is partitioned into a plurality of image regions and a LUT is chosen and used for each image region (local histogram equalization) (for example, see JP 2000-57335A (pg. 3, Figs. 13 to 16)).

Visual processing that combines spatial processing and gradation processing also is known. Conventional visual processing that combines spatial processing and gradation processing is described below using Fig. 48 and Fig. 51.

Fig. 48 shows a visual processing device 400 that performs edge enhancement and contrast enhancement utilizing unsharp masking. The visual processing device 400 shown in Fig. 48 is provided with a spatial processing portion 401 that performs spatial processing with respect to the input signal IS and outputs an unsharp signal US, a subtracting portion 402 that subtracts the unsharp signal US from the input signal IS and outputs a difference signal DS, an enhancing portion 403 that performs enhancement of the difference signal DS and outputs an enhanced signal TS, and a summing portion 404 that takes the sum of the input signal IS and the enhanced signal TS and outputs an output signal OS.

Here, enhancement processing is performed with respect to the difference signal DS using a linear or non-linear enhancement function. Fig. 49 shows the enhancement functions R1 to R3. The horizontal axis in Fig. 49 marks the difference signal DS and the vertical axis marks the enhanced signal TS. The enhancement function R1 is an enhancement function that is linear with respect to the difference signal DS. The

enhancement function R1 is a gain adjustment function expressed for example by $R1(x) = 0.5x$ (where x is the value of the difference signal DS). The enhancement function R2 is a non-linear enhancement function with respect to the difference signal DS, and is a function that inhibits extreme contrasts. In other words, a greater inhibitory effect (an inhibitory effect due to a larger inhibition rate) is exhibited with respect to an input x having a large absolute value (where x is the value of the difference signal DS). For example, the enhancement function R2 is expressed by a graph having a smaller slope the larger the absolute value of the input x . The enhancement function R3 is a non-linear enhancement function for the difference signal DS that inhibits the noise component in small amplitudes. That is, a greater inhibitory effect (an inhibitory effect due to a larger inhibition rate) is attained with respect to an input x having a small absolute value (where x is the value of the difference signal DS). For example, the enhancement function R3 is expressed by a graph having a larger slope the greater the absolute value of the input x . The enhancing portion 403 can use any of these enhancement functions R1 to R3.

The difference signal DS is the sharp component of the input signal IS. With the visual processing device 400, the intensity of the difference signal DS is transformed and added to the input signal IS. Thus, the output signal OS is the input signal IS in which the edges and the contrast have been enhanced.

Fig. 50 shows a visual processing device 406 that improves the local contrast (intensity) (for example, see Japanese Patent JP 2832954 (pg. 2, Fig. 5)). The visual processing device 406 shown in Fig. 50 is provided with a spatial processing portion 407, a subtracting portion 408, a first transformation portion 409, a multiplying portion 410, a second transformation portion 411, and a summing portion 412. The spatial

processing portion 407 performs spatial processing with respect to the input signal IS and outputs an unsharp signal US. The subtracting portion 408 subtracts the unsharp signal US from the input signal IS and outputs a difference signal DS. The first transformation portion 409 outputs an amplification coefficient signal GS for locally amplifying the difference signal DS based on the intensity of the unsharp signal US. The multiplying portion 410 takes the product of the difference signal DS and the amplification coefficient signal GS and outputs a contrast enhanced signal HS in which the difference signal DS has been locally amplified. The second transformation portion 411 locally corrects the intensity of the unsharp signal US and outputs a corrected unsharp signal AS. The summing portion 412 takes the sum of the contrast enhanced signal HS and the corrected unsharp signal AS and outputs an output signal OS.

The amplification coefficient signal GS is a non-linear weight coefficient that locally corrects the contrast in portions of the input signal IS where the contrast is unsuitable. For this reason, portions of the input signal IS having suitable contrast are output unchanged, and those portions with an unsuitable contrast are corrected and then output.

Fig. 51 shows a visual processing device 416 that performs compression of the dynamic range (for example, see JP 2001-298619A (pg. 3, Fig. 9)). The visual processing device 416 shown in Fig. 51 is provided with a spatial processing portion 417 that performs spatial processing with respect to the input signal IS and outputs an unsharp signal US, a LUT computation portion 418 that uses a LUT to perform an inverse transformation of the unsharp signal US to produce a LUT processed signal LS which it then outputs, and a summing portion 419 that takes the sum of the input signal IS and the LUT processed signal

LS and outputs an output signal OS.

The LUT processed signal LS is added to the input signal IS to compress the dynamic range of low-frequency components of the input signal IS (frequency components lower than the cutoff frequency of the spatial processing portion 417). As a result, the dynamic range of the input signal IS is compressed while its high-frequency components are retained.

Summary of the Invention

In the above visual processing, there is a need to obtain an image that has a better visual effect for the person who will view the visually processed image. For example, if the visually processed image is to be displayed, then the display environment will have an effect on how the image that is displayed will be viewed.

Accordingly, a goal of the present invention is to obtain an image that has a better visual effect for the person that will view the visually processed image.

The visual processing device according to claim 1 a first aspect of the invention comprises parameter output means and transformation means. The parameter output means outputs a luminance adjustment parameter based on a parameter expressing the ambient light. The transformation means transforms a luminance of a target pixel based on the luminance adjustment parameter that is output by the parameter output means, a luminance of a target pixel to be subjected to visual processing, and a luminance of surrounding pixels positioned in an area around the target pixel.

The parameter expressing the ambient light is for example measured by an optical sensor that senses the intensity of the light and input to the parameter output means. Alternatively, the parameter

expressing the ambient light can be created at the discretion of the user and then input to the parameter output means.

The luminance adjustment parameter is for example a lookup table (LUT) that stores the target pixel luminance after transformation
5 with respect to the luminance of the target pixel, the luminance of surrounding pixels, or the result of a computation involving these values, or coefficient matrix data for transforming the luminance of the target pixel, the luminance of surrounding pixels, or the result of a computation involving these values. The luminance adjustment parameter can also
10 include the parameter expressing the ambient light.

The parameter output means for example selects the luminance adjustment parameter corresponding to the parameter that expresses the ambient light from among a plurality of luminance adjustment parameters and outputs this, or creates a luminance adjustment
15 parameter based on a computation that incorporates the parameter expressing the ambient light and outputs this.

With the visual processing device according to this aspect of the invention, it is possible to achieve visual processing that is in correspondence with the ambient light. That is, it is possible to obtain
20 an image that has a better visual effect for the person who will view the visually processed image.

The visual processing device according to ~~claim 2~~ a second aspect of the invention is the visual processing device according to ~~claim 1~~ the first aspect of the invention in which the parameter output means
25 outputs the luminance adjustment parameter based on the parameter expressing the ambient light and an outside parameter that is input from an outside portion.

The outside parameter is a parameter that expresses a visual effect that is desired by the user who will view the image. More

specifically, it is a value such as the contrast desired by the user who will view the image (the same applies in the following description).

The parameter output means outputs the luminance adjustment parameter based on the parameter expressing the ambient light and the outside parameter. Here, the luminance adjustment parameter can for example also include the outside parameter.

With the visual processing device according to this aspect of the invention, it is possible to achieve visual processing that corresponds to the ambient light and the outside parameter. For example, the value of the contrast desired by the user who will view the image can be set by the user himself and thus an image that has a better visual effect from the perspective of the user can be obtained.

The visual processing device according to ~~claim 3~~ a third aspect of the invention is the visual processing device according to ~~claim 1~~ the first aspect of the invention in which the operation of the parameter output means is switched according to a switch signal, between a first mode of outputting the luminance adjustment parameter based on the parameter expressing the ambient light and a second mode of outputting the luminance adjustment parameter based on the parameter expressing the ambient light and an outside parameter that is input from an outside portion.

In the first mode, a luminance adjustment parameter that corresponds to the ambient light is output. In the second mode, a luminance adjustment parameter that corresponds to the ambient light and an outside parameter is output.

For example, in the first mode a predetermined luminance adjustment parameter that has been set in the system in advance is output. Also, for example in the second mode the user himself sets a value of the contrast, for example, at which he would like to view the

image, and a luminance adjustment parameter that correspondence to this set value and the ambient light is output.

With the visual processing device according to this aspect of the invention, it is possible to switch between using a value of the contrast, 5 for example, that has been set by the user who will view the image, and using a predetermined value that has been set in the system in advance.

The visual processing device according to claim 4-a fourth aspect of the invention is the visual processing device according to claim 1-the first aspect of the invention in which the transformation means performs 10 a computation for enhancing a difference or a ratio between the luminance of the target pixel and the luminance of the surrounding pixel.

Here, the computation for enhancing includes not only enhancement in the positive direction but also enhancement in the 15 negative direction. For example, it is inclusive of processing for smoothing the luminance of the target pixel and the luminance of the surrounding pixels, or processing for enhancing local contrast.

With the visual processing device according to this aspect of the invention, it is for example possible to enhance local contrast to maintain 20 the viewed contrast in an environment where ambient light is present.

The visual processing device according to claim 5-a fifth aspect of the invention is the visual processing device according to claim 1-the first aspect of the invention, further comprising a time change adjustment portion for controlling the change over time in the parameter expressing 25 the ambient light or the luminance adjustment parameter.

Here, the time change adjustment portion controls the change over time by easing the response to the change in the parameter over time, or delaying the response to the change in the parameter over time. In the case of easing the response, the time change adjustment portion

can be constituted by a smoothing filter such as an IIR filter or means that outputs a value obtained by integrating the values of the respective parameters or a value obtained by taking a mean of the integrated values.

5 With the visual processing device according to this aspect of the invention, by controlling the change over time in the parameter expressing the ambient light or the luminance adjustment parameter, it is possible to inhibit abrupt parameter fluctuations, and thus allows flickering in the displayed image to be inhibited.

10 The visual processing method according to ~~claim 6a~~ sixth aspect of the invention comprises a parameter output step and a transformation step. The parameter output step is a step of outputting a luminance adjustment parameter based on a parameter expressing the ambient light. The transformation step is a step of transforming a luminance of
15 a target pixel based on the luminance adjustment parameter that is output through the parameter output step, a luminance of a target pixel to be subjected to visual processing, and a luminance of surrounding pixels positioned in an area around the target pixel.

 The parameter expressing the ambient light is for example
20 measured by an optical sensor that senses the intensity of the light. Alternatively, the parameter expressing the ambient light can be created at the discretion of the user.

 The luminance adjustment parameter is for example a lookup table (LUT) that stores the target pixel luminance after transformation
25 with respect to the luminance of the target pixel, the luminance of surrounding pixels, or the result of a computation involving these values, or coefficient matrix data for transforming the luminance of the target pixel, the luminance of surrounding pixels, or the result of a computation involving these values. The luminance adjustment parameter can also

include the parameter expressing the ambient light.

The parameter output step is for example a step of selecting and outputting the luminance adjustment parameter corresponding to the parameter that expresses the ambient light from among a plurality of
5 luminance adjustment parameters, or of creating a luminance adjustment parameter based on a computation that incorporates the parameter expressing the ambient light and outputting this.

With the visual processing method according to this aspect of the invention, it is possible to achieve visual processing that corresponds to
10 the ambient light. That is, it is possible to perform visual processing that yields a better visual effect.

The visual processing program according to ~~claim 7~~ a seventh aspect of the invention is a program that causes a computer to perform a visual processing method. The visual processing method comprises a
15 parameter output step and a transformation step. The parameter output step is a step of outputting a luminance adjustment parameter based on a parameter expressing the ambient light. The transformation step is a step of transforming a luminance of a target pixel based on the luminance adjustment parameter that is output through the parameter
20 output step, a luminance of a target pixel to be subjected to visual processing, and a luminance of surrounding pixels positioned in an area around the target pixel.

The parameter expressing the ambient light is for example measured by an optical sensor that senses the intensity of the light.
25 Alternatively, the parameter expressing the ambient light can be created at the discretion of the user.

The luminance adjustment parameter is for example a lookup table (LUT) that stores the target pixel luminance after transformation with respect to the luminance of the target pixel, the luminance of

surrounding pixels, or the result of a computation involving these values, or coefficient matrix data for transforming the luminance of the target pixel, the luminance of surrounding pixels, or the result of a computation involving these values. The luminance adjustment parameter can also
5 include the parameter expressing the ambient light.

The parameter output step is for example a step of selecting and outputting the luminance adjustment parameter corresponding to the parameter that expresses the ambient light from among a plurality of luminance adjustment parameters, or of creating a luminance
10 adjustment parameter based on a computation that incorporates the parameter expressing the ambient light and outputting this.

With the visual processing program according to this aspect of the invention, it is possible to achieve visual processing that is in correspondence with the ambient light. That is, it is possible to perform
15 visual processing that yields a better visual effect.

The semiconductor device according to ~~claim 8~~ an eighth aspect of the invention comprises a parameter output portion and a transformation portion. The parameter output portion outputs a luminance adjustment parameter based on a parameter expressing the
20 ambient light. The transformation portion transforms a luminance of a target pixel based on the luminance adjustment parameter that is output by the parameter output portion, a luminance of the target pixel to be subjected to visual processing, and a luminance of surrounding pixels positioned in an area around the target pixel.

25 The parameter expressing the ambient light is for example measured by an optical sensor that senses the intensity of the light and input to the parameter output portion. Alternatively, the parameter expressing the ambient light can be created at the discretion of the user and then input to the parameter output portion.

The luminance adjustment parameter is for example a lookup table (LUT) that stores the target pixel luminance after transformation with respect to the luminance of the target pixel, the luminance of surrounding pixels, or the result of a computation involving these values, or coefficient matrix data for transforming the luminance of the target pixel, the luminance of surrounding pixels, or the result of a computation involving these values. The luminance adjustment parameter can also include the parameter expressing the ambient light.

The parameter output portion for example selects and then outputs a luminance adjustment parameter corresponding to the parameter that expresses the ambient light from among a plurality of luminance adjustment parameters, or creates a luminance adjustment parameter based on a computation that incorporates the parameter expressing the ambient light and outputs this.

With the semiconductor device according to this aspect of the invention, it is possible to achieve visual processing that is in correspondence with the ambient light. That is, it is possible to perform visual processing that yields a better visual effect.

With the visual processing device according to the present invention, it is possible to obtain an image that has a better visual effect for the user who will view the visually processed image.

Detailed Description of the Invention

15 Hereinafter, first through fourth embodiments serving as best modes for implementing the present invention will be described.

The first embodiment describes a visual processing device that employs a two-dimensional LUT.

20 The second embodiment describes a visual processing device that performs correction of the ambient light when ambient light is present in the environment in which the image is to be displayed.

The third embodiment describes applied examples of the first embodiment and the second embodiment.

25 The fourth embodiment describes applied examples of the first through third embodiments.

[First Embodiment]

A visual processing device 1 that employs a two-dimensional LUT is described below as a first embodiment of the present invention using

Figs. 1 to 10. A modified example of this visual processing device is described using Figs. 11 to 14. Further, a visual processing device that achieves visual processing that is equivalent to that of the visual processing device 1 is described using Figs. 15 to 23.

5 The visual processing device 1 is a device for performing visual processing such as spatial processing and gradation processing of an image signal. The visual processing device 1, together with a device that performs color processing of an image signal, constitutes an image processing device in a device that handles images, such as a computer, a
10 television, a digital camera, a portable telephone, a PDA, a printer, or a scanner.

<Visual Processing Device 1>

Fig. 1 shows the basic structure of the visual processing device 1, which performs visual processing of an image signal (input signal IS)
15 and outputs the result as a visually processed image (output signal OS). The visual processing device 1 is provided with a spatial processing portion 2 that performs spatial processing of the luminance value of each pixel of an original image that has been obtained as an input signal IS and outputs the result as an unsharp signal US, and a visual processing
20 portion 3 that performs visual processing of the original image using the input signal IS and the unsharp signal US for the same pixel and outputs the result as an output signal OS.

The spatial processing portion 2 for example obtains the unsharp signal US with a low-pass spatial filter that permits the passage of only
25 the low-frequency space of the input signal IS. As the low-pass spatial filter it is possible to use a FIR (Finite Impulse Response)-type low-pass spatial filter or an IIR (Infinite Impulse Response)-type low-pass spatial filter, which are commonly used to create unsharp signals.

The visual processing portion 3 has a two-dimensional LUT 4

that lists the relationship between the input signal IS and the unsharp signal US, and the output signal OS, and references the two-dimensional LUT 4 with the input signal IS and the unsharp signal US and outputs an output signal OS.

5 <Two-Dimensional LUT 4>

Matrix data referred to as profile data are registered to the two-dimensional LUT 4. The profile data has a row (or column) for each pixel value of the input signal IS and a column (or row) for each pixel value of the unsharp signal US, and the pixel values of the output signal
10 OS that correspond to the combination of the input signal IS and the unsharp signal US are stored as elements of the rows and columns. The profile data are registered to the two-dimensional LUT 4 by a profile data registration device 8 that is provided in or connected to the visual processing device 1. The profile data registration device 8 stores data of
15 a plurality of profiles that have been created in advance by a personal computer (PC) or the like. For example, it stores data of a plurality of profiles for achieving contrast enhancement, D-range compression, or gradation correction, for example (for a more detailed description, see the section <Profile Data> below). Thus, with the visual processing
20 device 1, the profile data registration device 8 can be used to change the profile data registered to the two-dimensional LUT 4, and this allows a variety of types of visual processing to be achieved.

An example of the profile data is shown in Fig. 2. The profile data shown in Fig. 2 causes the visual processing device 1 to execute
25 processing equivalent to that of the visual processing device 400 shown in Fig. 48. In Fig. 2, the profile data takes the form of a 64×64 matrix in which the values of the upper six bits of the luminance values of the 8-bit input signal IS are shown in the column direction (vertical direction) and the value of the upper six bits of the luminance value of

the 8-bit unsharp signal US are shown in the row direction (horizontal direction). The value of the output signal OS is expressed in 8 bits value as the matrix element corresponding to the two luminance values.

The value C of each element of the profile data shown in Fig. 2
5 (the value of the output signal OS) is expressed as $C = A + 0.5*(A-B)$ (hereinafter, this is referred to as Equation M11), using the value A of the input signal IS (which is a value obtained by discarding the lower two bits of the 8 bit input signal IS) and the value B of the unsharp signal US (which is a value that is obtained by discarding the lower two
10 bits of the 8-bit unsharp signal US). In other words, it can be seen that the visual processing device 1 performs processing equivalent to processing by the visual processing device 400 (see Fig. 48) using the enhancement function R1 (see Fig. 49).

It should be noted that depending on the combination of the value
15 A of the input signal IS and the value B of the unsharp signal US, the value C obtained from Eq. M11 may be a negative value. In this case, the element of the profile data corresponding to the value A of the input signal IS and the value B of the unsharp signal US may be set to the value 0. Further, depending on the combination of the value A of the
20 input signal IS and the value B of the unsharp signal US, the value C obtained from Eq. M11 may be saturated. That is, it may exceed the maximum value of 255 that can be expressed with 8 bits. In this case, the element of the profile data corresponding to the value A of the input signal IS and the value B of the unsharp signal US may be set to the
25 value 255. In Fig. 2, the elements of the profile data found in this manner are shown by contour line.

When using profile data in which the value C of the elements is expressed as $C = R6(B) + R5(B) * (A-B)$ (hereinafter, this is referred to as Equation M12), processing equal to that of the visual processing device

406 shown in Fig. 50 can be achieved. Here, the function R5 is that of
the first transformation portion 409 outputting an amplification
coefficient signal GS from the unsharp signal US, and the function R6 is
that of the second transformation portion 411 outputting a corrected
5 unsharp signal AS from the unsharp signal US.

When using profile data in which the values C of the elements are
expressed by $C = A + R8(B)$ (hereinafter, this is referred to as Equation
M13), processing equivalent to that of the visual processing device 416
shown in Fig. 51 can be achieved. Here, the function R8 is that of
10 outputting a LUT processed signal LS from the unsharp signal US.

It should be noted that if the value C of a particular element of
the profile data found through Eq. M12 or Eq. M13 is outside the range
 $0 \leq C \leq 255$, then the value C of that element can be regarded as 0 or 255.

<Visual Processing Method and Visual Processing Program>

15 Fig. 3 shows a flowchart that describes the visual processing
method of the visual processing device 1. The visual processing method
shown in Fig. 3 is a method for performing visual processing of an input
signal IS (see Fig. 1), and is achieved by the hardware in the visual
processing device 1.

20 With the visual processing method shown in Fig. 3, an input
signal IS is spatially processed by the low-pass spatial filter (step S11)
to obtain an unsharp signal US. The value of the two-dimensional LUT 4
that corresponds to the input signal IS and the unsharp signal US is
looked up and this value is output as the output signal OS (step S12).
25 The above processing is performed for each pixel that is received as an
input signal IS.

It should be noted that each step of the visual processing method
shown in Fig. 3 can also be achieved on a computer, for example, as a
visual processing program.

<Effects>

(1)

When visual processing is performed based on only the value A of the input signal IS (for example, in the case of performing a transformation based on a one-dimensional gradation transformation curve), if pixels having the same darkness are present at different areas in the image, then the two are transformed to the same brightness. More specifically, when brightening a dark area in the background of a person in an image, hair of that person having the same darkness will also be brightened.

In contrast to this, the visual processing device 1 performs visual processing using profile data that have created based on a two-dimensional function and correspond to the value A of an input signal IS and the value B of an unsharp signal US. For this reason, pixels having the same darkness that are present at different areas within the image are not transformed uniformly but instead can be made brighter or darker taking into account information on their surroundings, and this allows each region of the image to be adjusted to an ideal brightness. More specifically, a background that has the same darkness as the hair of a person in the image can be brightened without changing the darkness of the hair.

(2)

With the visual processing device 1, visual processing of the input signal IS is performed using the two-dimensional LUT 4. The visual processing device 1 has a hardware configuration that is independent of the visual processing effect that is to be achieved. That is, the visual processing device 1 can be constituted by generalized hardware, and this is useful for reducing hardware costs, for example.

(3)

The profile data that are registered to the two-dimensional LUT 4 can be changed by the profile data registration device 8. Thus, by changing the profile data it is possible for the visual processing device 1 to achieve various types of visual processing, without changing the hardware configuration of the visual processing device 1. More specifically, the visual processing device 1 is capable of simultaneously executing spatial processing and gradation processing.

(4)

The profile data that are registered to the two-dimensional LUT 4 can be calculated in advance. For profile data that have been created already, the amount of time required for visual processing using those data is the same regardless of the complexity of the processing. Thus, it is possible to increase the speed of visual processing by using the visual processing device 1 because the processing time does not depend on the complexity of the visual processing, even if the visual processing requires a complex structure when configured by hardware or software.

<Modified Examples>

(1)

Fig. 2 shows profile data in the form of a 64×64 matrix. Here, the effect of the present invention does not depend on the size of the profile data. For example, the two-dimensional LUT 4 can also have profile data that correspond to all the combinations of values possible from the input signal IS and the unsharp signal US. For example, if the input signal IS and the unsharp signal US are expressed with 8 bits, then the profile data can take the form of a 256×256 matrix.

In this case, although the memory capacity required for the two-dimensional LUT 4 increases, more accurate visual processing can be achieved.

(2)

In Fig. 2, the profile data have been explained as storing the values of the output signals OS for the values of the upper six bits of the luminance value of the 8-bit input signal IS and the values of the upper six bits of the luminance value of the 8-bit unsharp signal US. Here, it is also possible that the visual processing device 1 is further provided with an interpolation portion that performs linear interpolation of the value of the output signal OS based on the adjacent elements of the profile data and the size of the lower two bits of the input signal IS and the unsharp signal US.

In this case, more accurate visual processing can be achieved without increasing the memory capacity necessary for the two-dimensional LUT 4.

The interpolating portion may be provided in the visual processing portion 3 and may output as an output signal OS a value that is obtained by linearly interpolating the values stored in the two-dimensional LUT 4.

Fig. 4 shows a visual processing portion 500 provided with an interpolating portion 501, as a modified example of the visual processing portion 3. The visual processing portion 500 is provided with a two-dimensional LUT 4 that lists the relationship between an input signal IS and an unsharp signal US and a pre-interpolation output signal NS, and the interpolating portion 501, which receives the pre-interpolation output signal NS, the input signal IS and the unsharp signal US and outputs an output signal OS.

The two-dimensional LUT 4 stores the values of the pre-interpolation output signal NS for the values of the upper six bits of the luminance of the 8-bit input signal IS and the values of the upper six bits of the luminance of the 8-bit unsharp signal US. The values of the pre-interpolation output signal NS are for example stored as 8-bit values.

When the two-dimensional LUT 4 receives the 8-bit value of the input signal IS and the 8-bit value of the unsharp signal US, it outputs the values of the four pre-interpolation output signals NS corresponding to the section including each of the values. The section including each of
5 the values is the section surrounded by the four pre-interpolation output signals NS stored for the combinations of (the value of the upper six bits of the input signal IS, the value of the upper six bits of the unsharp signal US), (the smallest six-bit value that exceeds the value of the upper six bits of the input signal IS, the value of the upper six bits of the
10 unsharp signal US), (the value of the upper six bits of the input signal IS, the smallest six-bit value that exceeds the value of the upper six bits of the unsharp signal US), and (the smallest six-bit value that exceeds the value of the upper six bits of the input signal IS, the smallest six-bit value that exceeds the value of the upper six bits of the unsharp signal
15 US).

The value of the lower two bits of the input signal IS and the value of the lower two bits of the unsharp signal US are input to the interpolating portion 501, and using these values, the interpolating portion 501 performs linear interpolation of the values of the four
20 pre-interpolation output signals NS output by the two-dimensional LUT 4. More specifically, the interpolating portion 501 uses the value of the lower two bits of the input signal IS and the value of the lower two bits of the unsharp signal US to calculate the weighted mean of the values of the four pre-interpolation output signals NS, and outputs this as the
25 output signal OS.

Through the above, more accurate visual processing can be achieved without increasing the memory capacity required for the two-dimensional LUT 4.

It should be noted that it is also possible for the interpolating

portion 501 to perform linear interpolation of only one of either the input signal IS or the unsharp signal US.

(3)

With the spatial processing performed by the spatial processing portion 2, as the unsharp signal US for the input signal IS of a pixel being processed it is also possible to output the mean value (simple mean or weighted mean), the maximum value, the minimum value, or the median value of the input signal IS of the pixel being processed and the pixels surrounding the pixel being processed. It is further possible to output the mean value (simple mean or weighted mean), the maximum value, the minimum value, or the median value of only the pixels surrounding the pixel being processed as the unsharp signal US.

(4)

In Fig. 2, the values C of the elements of the profile data are created based on the linear function M11 performed with respect to each of the value A of the input signal IS and the value B of the unsharp signal US. However, it is also possible to create the values C of the elements of the profile data based on a non-linear function with respect to the value A of the input signal IS.

In this case, it is possible to achieve visual processing that corresponds to the viewing properties or visual processing that is suited for the non-linear characteristics of a device that handles images, such as a computer, a television, a digital camera, a portable telephone, a PDA, a printer, or a scanner, that outputs an output signal OS.

It is also possible to create the value C of the each element of the profile data based on a non-linear function of the value A of the input signal IS and the value B of the unsharp signal US, that is, a two-dimensional non-linear function.

For example, when visual processing is performed based on only

the value A of the input signal IS (for example, in the case of performing a transformation based on a one-dimensional gradation transformation curve), if pixels having the same darkness are present at different areas in the image, then the two are transformed to the same brightness.

- 5 More specifically, when brightening a dark area in the background of a person in an image, hair of that person having the same darkness will also be brightened.

On the other hand, if visual processing is performed using profile data that have been created based on a two-dimensional non-linear function, pixels having the same darkness that are present at different areas within the image are not transformed uniformly but instead can be made brighter or darker taking into account surrounding information, and this allows each region of the image to be adjusted to an ideal brightness. More specifically, a background that has the same darkness as the hair of a person in the image can be brightened without changing the darkness of the hair. Moreover, it is also possible to perform visual processing in which the gradation is maintained, even for those image regions in which the pixel values become saturated after visual processing according to a linear function.

- 20 Fig. 5 shows an example of such profile data. The profile data shown in Fig. 5 are profile data with which the visual processing device 1 can perform contrast enhancement that is suited for the visual characteristics. In Fig. 5, the profile data are expressed as a 64×64 matrix, in which the value of the upper six bits of the luminance value of the 8-bit input signal IS is shown in the column direction (vertical direction) and the value of the upper six bits of the luminance value of the 8-bit unsharp signal US is shown in the row direction (horizontal direction). The output signal OS is expressed as an 8-bit value as the matrix element corresponding to the two luminance values.
- 25

The values C of the elements of the profile data shown in Fig. 5 (the values of the output signal OS) can be expressed by $C = F2(F1(A)+F3(F1(A)-F1(B)))$ (hereinafter, this is referred to as Equation M14), using the value A of the input signal IS (which is a value obtained by discarding the lower two bits of the 8 bit input signal IS, for example), the value B of the unsharp signal US (which is a value that is obtained by discarding the lower two bits of the 8-bit unsharp signal US, for example), a transformation function F1, an inverse transformation function F2 of that transformation function, and an enhancement function F3. Here, the transformation function F1 is a common logarithmic function. The inverse transformation function F2 is an exponential function (antilog) that functions as the inverse function of the common logarithmic function. The enhancement function F3 is any of the enhancement functions R1 to R3 explained using Fig. 49.

These profile data allow visual processing using an input signal IS and an unsharp signal US that have been transformed to logarithmic space by the transformation function F1. Human visual performance is logarithmic, and visual processing that is suited for our visual performance is best achieved by performing processing after transforming to logarithmic space. Due to this, the visual processing device 1 performs contrast enhancement in logarithmic space.

It should be noted that depending on the combination of the value A of the input signal IS and the value B of the unsharp signal US, the value C obtained from Eq. M14 may be a negative value. In this case, the element of the profile data corresponding to the value A of the input signal IS and the value B of the unsharp signal US may be set to the value 0. Further, depending on the combination of the value A of the input signal IS and the value B of the unsharp signal US, the value C that is obtained from Eq. M14 may be saturated. That is, it may exceed

the maximum value of 255 that can be expressed with 8 bits. In this case, the element of the profile data corresponding to the value A of the input signal IS and the value B of the unsharp signal US may be set to the value 255. In Fig. 5, each element of the profile data found in this manner is shown by a contour line.

Non-linear profile data are described in more specific detail in the section <Profile Data> below.

(5)

It is also possible for the profile data of the two-dimensional LUT 4 to include a plurality of gradation transformation curves (gamma curves) for correcting the gradation of the input signal IS.

Each gradation transformation curve is a ~~monotonously~~monotonically increasing function such as a gamma function that has different gamma coefficients, and is associated with the value of the unsharp signal US. This association is performed such that gamma functions having large gamma coefficients are selected for the values of small unsharp signals US, for example. Thus, the unsharp signal US can function as a selection signal for selecting at least one gradation transformation curve from the gradation transformation curve group included in the profile data.

According to the above configuration, the gradation of the value A of the input signal IS is transformed using a gradation transformation curve that has been selected by the value B of the unsharp signal US.

It should be noted that it is also possible to interpolate the output of the two-dimensional LUT 4 as described in (2) above.

(6)

It was explained above that the profile data registration device 8 is provided in or connected to the visual processing device 1, stores data of a plurality of profiles created in advance by a PC or the like, and can

be used to change the content registered to the two-dimensional LUT 4.

Here, the profile data stored in the profile data registration device 8 are created by a PC that is disposed outside of the visual processing device 1. The profile data registration device 8 obtains the
5 profile data from the PC over a network or via a recording medium.

The profile data registration device 8 registers data of a plurality of profiles to be stored to the two-dimensional LUT 4 in accordance with a predetermined condition. This is described in greater detail using Figs. 6 to 8. It should be noted that portions having substantially the
10 same function as in the visual processing device 1, which was described above using Fig. 1, are assigned identical reference numerals and further description thereof is omitted.

<<1>>

Fig. 6 is a block diagram of a visual processing device 520 that
15 determines the image of an input signal IS, and based on the results of this determination, switches the profile data registered to the two-dimensional LUT 4.

The visual processing device 520, in addition to the same structural components as the visual processing device 1 shown in Fig. 1,
20 also has a profile data registration portion 521 that has the same function as the profile data registration device 8. The visual processing device 520 is further provided with an image determination portion 522.

The image determination portion 522 receives an input signal IS and outputs determination results SA of the input signal IS. The profile
25 data registration portion 521 receives the determination results SA and outputs profile data PD selected based on those determination results SA.

The image determination portion 522 determines the image of the input signal IS. In this determination of the image, the brightness of

the input signal IS is determined by obtaining a pixel value such as the luminance or the brightness of the input signal IS.

The profile data registration portion 521 obtains the determination results SA, and based on these determination results SA, it switches the profile data PD and outputs the result. More specifically, if the input signal IS is determined to be bright, then profile data that compress the dynamic range, for example, are selected. By doing this, the contrast can be maintained even for images that are bright overall. Also, a profile with an output signal OS having a suitable dynamic range for the characteristics of the device that will display the output signal OS is selected.

Thus, the visual processing device 520 is capable of suitably visually processing an input signal IS.

It should be noted that it is also possible for the image determination portion 522 to determine an image characteristic, such as the spatial frequency, in addition to a pixel value such as the luminance or the brightness of the input signal IS.

In this case, it is possible to achieve more suitable visual processing, such as the selection of a profile that leads to a higher degree of sharpness enhancement with respect to an input signal IS whose spatial frequency is low.

<<2>>

Fig. 7 is a block diagram of a visual processing device 525 that switches the profile data registered to the two-dimensional LUT 4 based on the results of an input from an input device for inputting conditions relating to the brightness.

The visual processing device 525, in addition to the same structural components as the visual processing device 1 shown in Fig. 1, also is provided with a profile data registration portion 526 that has the

same function as the profile data registration device 8. The visual processing device 525 is provided with an input device 527 to which it is connected through a wired or a wireless connection. More specifically, the input device 527 can be achieved for example by an input button
5 provided on, or remote control for, a device that handles images, such as a computer, a television, a digital camera, a portable telephone, a PDA, a printer, or a scanner, that outputs an output signal OS.

The input device 527 is an input device for inputting conditions related to the brightness, and for example is provided with switches such
10 as "bright" and "dark." The input device 527 outputs the input results SB through control by a user.

The profile data registration portion 526 obtains the input results SB, and based on the input results SB switches the profile data PD and outputs the result. More specifically, for example if the user has input
15 "bright," then a profile for compressing the dynamic range of the input signal IS, for example, is selected and this is output as the profile data PD. Thus, the contrast can be maintained even if the device for displaying the output signal OS has been placed in a "bright" environment.

20 Thus, with the visual processing device 525, it is possible to attain suitable visual processing that is in accordance with the input from the input device 527.

It should be noted that the conditions related to the brightness can be not only the conditions related to the brightness of the ambient
25 light around the medium that will output the output signal, such as a computer, digital camera, portable telephone, or PDA, but also can be the conditions related to the brightness of the medium itself to which the output signal will be output, such as the printer paper. The conditions can also be related to the brightness of the medium by which the input

signal is received, such as the scanner paper.

It is also possible for these conditions to be automatically input by a photo sensor, for example, instead of only being input through a switch or the like.

5 It should be noted that it is also possible for the input device 527 to be a device that directly causes the profile data registration portion 526 to change the profile rather than a device that simply inputs conditions related to brightness. In this case, the input device 527 can display a list of the profile data in addition to the conditions to the
10 related to the brightness, and have the user make a selection from among these.

By doing this, the user can perform visual processing that suits his personal tastes.

It should be noted that the input device 527 can also be a device
15 for authenticating the user. In this case, the input device 527 can be a device such as a camera that authenticates the user or a device through which the user inputs his or her user name.

For example, if the user indicates through the input device 527 that he or she is a child, then profile data for inhibiting extreme
20 luminance changes, for example, are selected.

Visual processing that is suited for the user thus can be achieved.

<<3>>

Fig. 8 is a block diagram of a visual processing device 530 that switches the profile data registered to the two-dimensional LUT 4 based
25 on the detection results from a luminance detection portion for detecting two types of brightness.

The visual processing device 530, in addition to the same structural components as the visual processing device 1 shown in Fig. 1, also has a profile data registration portion 531 that has the same

function as the profile data registration device 8. The visual processing device 530 is further provided with a brightness detection portion 532.

The brightness detection portion 532 comprises the image determination portion 522 and the input device 527. The image determination portion 522 and the input device 527 are the same as those described using Figs. 6 and 7. Thus, the brightness detection portion 532 receives the input signal IS as input, and outputs the determination results SA from the image determination portion 522 and the input results SB from the input device 527 as detection results.

The profile data registration portion 531 receives the determination results SA and the input results SB as input, and based on the determination results SA and the input results SB, switches the profile data PD and outputs the result. More specifically, for example if the ambient light is "bright" and it also has been determined that the input signal IS is bright, then a profile that compresses the dynamic range of the input signal IS, for example, is selected and this is output as the profile data PD. Thus, the contrast can be maintained when the output signal OS is displayed.

Thus, with the visual processing device 530, it is possible to achieve suitable visual processing.

<<4>>

In the visual processing devices of Figs. 6 to 8, it is not necessary to provide the profile data registration portion in a single unit with the visual processing device. More specifically, the profile data registration portions can be connected to the visual processing devices over a network as a server provided with a plurality of profile data sets or as a plurality of servers each provided with profile data. Here, the network is a wired or wireless connection means that is capable of communication, such as a dedicated telephone line, a public telephone line, the Internet, or a LAN.

In this case, the determination results SA and the input results SB both are transferred from the visual processing device side to the profile data registration portion side over the same network.

(7)

5 In the above embodiment, it was explained that the profile data registration device 8 is provided with a plurality of profile data sets, and different visual processing was achieved by switching which of these is registered to the two-dimensional LUT 4.

10 Here, it is also possible for the visual processing device 1 to be provided with a plurality of two-dimensional LUT, each being provided with profile data for achieving a different visual processing. In this case, the visual processing device 1 achieves different visual processing by switching which of the two-dimensional LUTs receives the input or by switching which of the two-dimensional LUTs to receive the output from.

15 In this case, the memory capacity that must be secured for the two-dimensional LUT increases, but the time required for switching between the different visual processing types can be shortened.

 It is also possible for the profile data registration device 8 to be provided with a device that creates new profile data based on data of a plurality of profiles and registers the profile data that are created to the two-dimensional LUT 4.

 This implementation is described using Figs. 9 and 10.

25 Fig. 9 is a block diagram that primarily illustrates a profile data registration device 701, as a modified example of the profile data registration device 8. The profile data registration device 701 is a device for switching the profile data that are registered to the two-dimensional LUT 4 of the visual processing device 1.

 The profile data registration device 701 comprises a profile data registration portion 702 to which a plurality of profile data sets are

registered, a profile creation execution portion 703 that creates new profile data based on the data of a plurality of profiles, a parameter input portion 706 for inputting parameters with which to create new profile data, and a control portion 705 that controls these portions.

5 Data of a plurality of profiles are registered to the profile data registration portion 702 as in the profile data registration device 8 or the profile data registration portions shown in Fig. 6 to Fig. 8, and the profile data that have been selected through a control signal C10 from the control portion 705 are read out. Here, data of two selected profiles
10 are read out from the profile data registration portion 702, namely first selected profile data d10 and second selected profile data d11.

 The profile data that are read from the profile data registration portion 702 are determined based on input from the parameter input portion 706. The parameter input portion 706, either manually or
15 automatically from a sensor or the like, receives the desired visual processing effect, the degree of that processing, or information relating to the viewing environment of the image to be processed, as a parameter. From the parameter input by the parameter input portion 706, the control portion 705 specifies the profile data to be read out with a control
20 signal c10 and also specifies the value of the degree of synthesis of the respective profile data using a control signal c12.

 The profile creation execution portion 703 is provided with a profile creation portion 704 that produces a created profile data d6, which are new profile data, from the first selected profile data d10 and
25 the second selected profile data d11.

 The profile creation portion 704 obtains the first selected profile data d10 and the second selected profile data d11 from the profile data registration portion 702. It also obtains the control signal c12, which specifies the degree of synthesis of the respective selected profile data,

from the control portion 705.

The profile creation portion 704 then applies the value [k] of the degree of synthesis specified by the control signal c12 to a value [m] of the first selected profile data d10 and a value [n] of the second selected profile data d11 to create created profile data d6 having a value [l]. Here, the value [l] is calculated by $[l] = (1-k) * [m] + k * [n]$. It should be noted that if the value [k] is $0 \leq k \leq 1$, then the first selected profile data d10 and the second selected profile data d11 are interpolated, and if the value [k] is $k < 0$ or $k > 1$, then the first selected profile data d10 and the second selected profile data d11 are extrapolated.

The two-dimensional LUT 4 obtains the created profile data d6 created by the profile creation portion 704 and stores the obtained value in an address that is specified by a count signal c11 of the control portion 705. Here, the created profile data d6 are associated with the same image signal value as the selected profile data that were used to create the created profile data d6.

Thus, profile data that achieve different visual processing can be used to create new profile data that achieve yet different visual processing.

The visual processing profile creation method that is executed by the visual processing device provided with the profile data registration device 701 is described using Fig. 10.

The address of the profile data registration portion 702 is specified at a fixed count period by a count signal c10 from the control portion 705, and the image signal value that is stored in the specified address is read out (step S701). More specifically, the control portion 705 outputs a count signal c10 in correspondence with a parameter that has been input by the parameter input portion 706. The count signal c10 specifies the addresses of two profile data, each of which achieves

different visual processing, in the profile data registration portion 702. From this signal, the first selected profile data d10 and the second selected profile data d11 are read from the profile data registration portion 702.

5 The profile creation portion 704 obtains the control signal c12, which specifies the degree of synthesis, from the control portion 705 (step S702).

 The profile creation portion 704 then applies the value [k] of the degree of synthesis specified by the control signal c12 to the value [m] of
10 the first selected profile data d10 and the value [n] of the second selected profile data d11 to create a created profile data d6 having the value [l] (step S703). Here, the value [l] is calculated by $[l] = (1-k) * [m] + k * [n]$.

 The created profile data d6 are written to the two-dimensional LUT 4 (step S704). The address to which the data are written is
15 specified by a count signal c11 from the control portion 705 that is given to the two-dimensional LUT 4.

 The control portion 705 determines whether or not processing has finished for all of the selected profile data (step S705), and repeats the processes of step S701 to step S705 until this processing is finished.

20 The new profile data stored in the two-dimensional LUT 4 in this manner are then used to execute visual processing.

<<Effect of (7)>>

 With the visual processing device provided with the profile data registration device 701, profile data that achieve different visual
25 processing can be used to create new profile data that achieve yet different visual processing, and this visual processing can be performed. That is, it is possible to achieve visual processing to any degree simply by providing the profile data registration portion 702 with a small number of profile data, and thus the memory capacity of the profile data

registration portion 702 can be reduced.

It should be noted that the profile data registration device 701 can be provided not only in the visual processing device 1 shown in Fig. 1, but also in any of the visual processing devices of Figs. 6 to 8. In this case, the profile data registration portion 702 and the profile creation execution portion 703 are used in place of the profile data registration portions 521, 526, and 531 shown in Figs. 6 to 8, respectively, and the parameter input portion 706 and the control portion 705 are used in place of the image determination portion 522 of Fig. 6, the input device 527 of Fig. 7, and the brightness detection portion 532 of Fig. 8.

(8)

The visual processing device can also be a device that transforms the brightness of the input signal IS. A visual processing device 901 that transforms the brightness is described using Fig. 11.

<<Configuration>>

The visual processing device 901 is a device that transforms the brightness of an input signal IS', and includes a processing portion 902 that performs a predetermined processing with respect to the input signal IS' and outputs a processed signal US', and a transformation portion 903 that uses the input signal IS' and the processed signal US' to perform transformation of the input signal IS'.

The processing portion 902 operates in the same manner as the spatial processing portion 2 (see Fig. 1), and performs spatial processing of the input signal IS'. It should be noted that it can also perform spatial processing such as that discussed in the above <Modified Example> (3).

The transformation portion 903 is provided with a two-dimensional LUT like the visual processing portion 3 and outputs an output signal OS' (value [y]) based on the input signal IS' (value [x]) and

the processed signal US' (value [z]).

Here, the values of the elements of the two-dimensional LUT of the transformation portion 903 are determined by applying the value [x] of the input signal IS' to gain or offset that has been determined in
5 correspondence with the value of the function $f_k(z)$, which is related to the extent of change in brightness. The function $f_k(z)$ related to the extent of change in brightness is hereinafter referred to as the "extent change function."

The value of each element of the two-dimensional LUT (=the
10 value [y] of the output signal OS') is determined according to a function relating the value [x] of the input signal IS' and the value [z] of the processed signal US'. Hereinafter, this function is referred to as a "transformation function," and the transformation functions (a) to (d) are examples thereof. Figs. 12(a) to (d) show the relationship between the
15 input signal IS' and the output signal OS' when the extent change function $f_k(z)$ has been changed.

<<Regarding the Transformation Function (a)>>

The transformation function (a) is expressed as $[y] = f_1(z) * [x]$.

Here, the extent change function $f_1(z)$ acts as gain of the input
20 signal IS'. Thus, the gain of the input signal IS' changes depending on the value of the extent change function $f_1(z)$, and this changes the value [y] of the output signal OS'.

Fig. 12(a) shows the change in the relationship between the input signal IS' and the output signal OS' for various values of the extent
25 change function $f_1(z)$.

The value [y] of the output signal increases as the extent change function $f_1(z)$ becomes larger ($f_1(z) > 1$). That is, the image after transformation becomes brighter. On the other hand, the value [y] of the output signal decreases as the extent change function $f_1(z)$ becomes

smaller ($f1(z)<1$). That is, the image after transformation becomes darker.

Here, the extent change function $f1(z)$ is a function in which the smallest value in the defined domain of the value $[z]$ does not become
5 less than $[0]$.

If due to the computation of the transformation function (a) the value $[y]$ of the output signal is outside the valid range of values, then it may be clipped to the valid range of values. For example, if the value $[y]$ of the output signal exceeds the value $[1]$, then it is possible to clip it
10 to the value $[1]$, and if the value $[y]$ of the output signal is below the value $[0]$, then it can be clipped to the value $[0]$. This also applies to the other transformation functions (b) through (d) discussed below.

<<Regarding the Transformation Function (b)>>

The transformation function (b) is expressed as $[y] = [x] + f2(z)$.

15 Here, the extent change function $f2(z)$ acts as offset of the input signal IS' . Thus, the offset of the input signal IS' changes depending on the value of the extent change function $f2(z)$, and this changes the value $[y]$ of the output signal OS' .

Fig. 12(b) shows the change in the relationship between the input
20 signal IS' and the output signal OS' when the value of the extent change function $f2(z)$ is changed.

The value $[y]$ of the output signal increases as the extent change function $f2(z)$ becomes larger ($f2(z)>0$). That is, the image after transformation becomes brighter. On the other hand, the value $[y]$ of
25 the output signal decreases as the extent change function $f2(z)$ becomes smaller ($f2(z)<0$). That is, the image after transformation becomes darker.

<<Regarding the Transformation Function (c)>>

The transformation function (c) is expressed as $[y] = f1(z) * [x] +$

$f2(z)$.

Here, the extent change function $f1(z)$ acts as gain of the input signal IS' . The extent change function $f2(z)$ also acts as offset of the input signal IS' . Thus, the gain of the input signal IS' changes
5 depending on the value of the extent change function $f1(z)$, and the offset of the input signal IS' changes depending on the value of the extent change function $f2(z)$, and this changes the value $[y]$ of the output signal OS' .

Fig. 12(c) shows the change in the relationship between the input
10 signal IS' and the output signal OS' when the values of the extent change function $f1(z)$ and the extent change function $f2(z)$ are changed.

The value $[y]$ of the output signal increases as the extent change function $f1(z)$ and the extent change function $f2(z)$ become larger. That is, the image after transformation becomes brighter. On the other hand,
15 the value $[y]$ of the output signal decreases as the extent change function $f1(z)$ and the extent change function $f2(z)$ become smaller. That is, the image after transformation becomes darker.

<<Regarding the Transformation Function (d)>>

The transformation function (d) is expressed as $[y] = [x]$
20 $^{(1-f2(z))}$.

Here, the extent change function $f2(z)$ determines the “power” of the “power function.” Thus, the input signal IS' changes depending on the value of the extent change function $f2(z)$, and this changes the value $[y]$ of the output signal OS' .

Fig. 12(d) shows the change in the relationship between the input
25 signal IS' and the output signal OS' when the value of the extent change function $f2(z)$ is changed.

The value $[y]$ of the output signal increases as the extent change function $f2(z)$ becomes larger ($f2(z) > 0$). That is, the image after

transformation becomes brighter. On the other hand, the value [y] of the output signal decreases as the extent change function $f2(z)$ becomes smaller ($f2(z) < 0$). That is, the image after transformation becomes darker. If the extent change function $f2(z)$ is the value [0], then
5 transformation with respect to the input signal IS' is not performed.

It should be noted that the value [x] is a value obtained by normalizing the value of the input signal IS' to the range of [0] to [1].

<<Effect>>

(1)

10 With the visual processing device 901, visual processing of the input signal IS' is performed in accordance with a two-dimensional LUT that has elements that have been determined using one of the transformation functions (a) to (d) shown above. Each element of the two-dimensional LUT stores a value [y] with respect to a value [x] and a
15 value [z]. Thus, it is possible to achieve viewing angle processing in which the brightness of the input signal IS' is transformed based on the input signal IS' and the processed signal US'.

(2)

Here, if the extent change function $f1(z)$ and the extent change
20 function $f2(z)$ are both functions that decrease monotonically, then it is also possible to achieve the effect of backlight correction or to prevent blooming, for example. This is described in greater detail below.

Figs. 13(a) and (b) show examples in which the extent change function $f1(z)$ and the extent change function $f2(z)$ both decrease
25 monotonically. Each shows three graphs (a1 to a3, b1 to b3), and each of these graphs is an example of a function that decreases monotonically.

The extent change function $f1(z)$ is a function that has a value range that spans the value [1], and is a function in which the minimum value with respect to the defined range of the value [z] is not less than

the value [0]. The extent change function $f_2(z)$ is a function that has a value range that spans the value [0].

For example, in portions in the image in which the area of darkness is large, the value [z] of the processed signal US' is small. The value of the extent change function for a small value [z] is large. That is, when a two-dimensional LUT that has been created based on a transformation function (a) through (d) is used, then portions in the image in which the area of darkness is large are made brighter. Thus, for example in an image that is captured with backlight, the dark portions are fixed in sections in which the area of darkness is large, and this improves the visual effect.

Also, for example in portions in the image in which the area of brightness is large, the value [z] of the processed signal US' is large. The value of the extent change function for a large value [z] is small. That is, when a two-dimensional LUT that has been created based on a transformation function (a) through (d) is used, portions in the image in which the area of brightness is large are made darker. Thus, for example in an image having bright portions such as the sky, blooming is fixed in the portions in which the area of brightness is large, and this improves the visual effect.

<<<Modified Examples>>>

(1)

The transformation functions described above are only examples, and any functions are possible as long as transformation having the same characteristics is achieved.

(2)

It is not absolutely necessary that the value of each element of the two-dimensional LUT is determined by a transformation function discussed above.

For example, if the value of the above transformation functions is outside the range of values that can be adopted as the output signal OS', then the two-dimensional LUT can store values that have been clipped to a range of values that can be adopted as the output signal OS'.

5 (3)

It is also possible to perform the same processing as discussed above without using a two-dimensional LUT. For example, it is also possible for the transformation portion 903 to execute the transformation functions (a) to (d) with respect to the input signal IS' and the processed
10 signal US' and output the result as the output signal OS'.

(9)

It is also possible for the visual processing device to be provided with a plurality of spatial processing portions and for it to perform visual processing using a plurality of unsharp signals each spatially processed
15 to a different degree.

<<Configuration>>

Fig. 14 shows the configuration of a visual processing device 905. The visual processing device 905 is a device that performs visual processing of an input signal IS", and comprises a first processing
20 portion 906a that performs a first predetermined processing with respect to the input signal IS" and outputs a first processed signal U1, a second processing portion 906b that performs a second predetermined processing with respect to the input signal IS" and outputs a second processed signal U2, and a transformation portion 908 that uses the
25 input signal IS", the first processed signal U1, and the second processed signal U2 to perform transformation of the input signal IS".

The first processing portion 906a and the second processing portion 906b both operate in the same manner as the spatial processing portion 2 (see Fig. 1), and perform spatial processing of the input signal

IS". It should be noted that it is also possible for them to perform spatial processing such as that described in the <Modified Example> (3) above.

Here, the first processing portion 906a and the second processing
5 portion 906b differ in the size of the region of the surrounding pixels that are used for the spatial processing.

More specifically, the first processing portion 906a uses the surrounding pixels that are included in a region of 30 pixels vertically by 30 pixels horizontally with the target pixel in the center (small unsharp
10 signal), whereas the second processing portion 906b uses the surrounding pixels that are included in the region of 90 pixels vertically by 90 pixels horizontally with the target pixel in the center (large unsharp signal). It should be noted that the region of surrounding
15 limitation to this. It is preferable that the unsharp signal is created from a fairly wide region in order to obtain a sufficient visual processing effect.

The transformation portion 908 is provided with a LUT, and outputs an output signal OS" (value [y]) based on the input signal IS" (value [x]), the first processed signal U1 (value [z1]), and the second
20 processed signal U2 (value [z2]).

Here, the LUT that the transformation portion 903 is provided with is a three-dimensional LUT that stores values [y] of the output signal OS" with respect to the values [x] of the input signal IS", the
25 values [z1] of the first processed signal U1, and the values [z2] of the second processed signal U2. The value of each element of this three-dimensional LUT (= the values [y] of the output signal OS") is determined based on a function of the value [x] of the input signal IS', the value [z1] of the first processed signal U1, and the value [z2] of the

second processed signal U2.

This three-dimensional LUT is capable of achieving the processing discussed in the above-described and later-described embodiments, but here the three-dimensional LUT is described for the
5 <<Case of Transforming the Brightness of the Input Signal IS">> and the <<Case of Enhancement Transformation of the Input Signal IS">>.

<<Case of Transforming the Brightness of the Input Signal IS">>

The transformation portion 908 performs a transformation to brighten the input signal IS" if the value [z1] of the first processed signal
10 U1 is small. However, the extent to which it is brightened is kept low if the value [z2] of the second processed signal US also is small.

As examples of this transformation, the value of each element of the three-dimensional LUT of the transformation portion 903 is determined based on the following transformation function (e) or (f).

15 (Regarding the Transformation Function (e))

The transformation function (e) is expressed by $[y] = [f11(z1)/f12(z2)] * [x]$.

Here, the extent change functions f11(z1) and f12(z2) are the same function as the extent change function f1(z) described in <Modified
20 Example> (8) above. The extent change function f11(z1) and the extent change function f12(z2) are different functions.

Thus, $[f11(z1)/f12(z2)]$ acts as the gain of the input signal IS", and the gain of the input signal IS" changes in accordance with the value of the first processed signal U1 and the value of the second processed signal
25 U2, and this changes the value [y] of the output signal OS".

(Regarding the Transformation Function (f))

The transformation function (f) is expressed by $[y] = [x] + f21(z1) - f22(z2)$.

Here, the extent change functions f21(z1) and f22(z2) are the

same function as the extent change function $f2(z)$ described in <Modified Example> (8) above. The extent change function $f21(z1)$ and the extent change function $f22(z2)$ are different functions.

Thus, $[f21(z1) - f22(z2)]$ acts as the offset of the input signal IS",
5 and the offset of the input signal IS" changes in accordance with the value of the first processed signal U1 and the value of the second processed signal U2, and this changes the value [y] of the output signal OS".

(Effect)

10 Through transformation using the transformation functions (e) and (f), it is possible to achieve the effect of brightening dark areas in regions having a small area of backlight while keeping the large dark area region of nighttime images from being brightened too much.

(Modified Example)

15 It should be noted that the processing by the transformation portion 908 is not limited to processing using a three-dimensional LUT, and it can also be processing in which the same computations as those of the transformation functions (e) or (f), for example, are performed.

Also, it is not absolutely necessary that the elements of the
20 three-dimensional LUT are determined based on the transformation functions (e) or (f).

<<Case of Enhancement Transformation of the Input Signal IS">>

If the transformation by the transformation portion 908 is
25 transformation that enhances the input signal IS", then it is possible to independently enhance a plurality of frequency components.

In the case of a transformation further enhancing the first processed signal U1, it is possible to enhance dark portions in which the frequency is relatively high, whereas in the case of a transformation

further enhancing the second processed signal U2, it is possible to enhance dark portions in which the frequency is low.

<Profile Data>

The visual processing device 1 can also be provided with profile data for achieving various types of visual processing other than that described above. First through seventh profile data for achieving various types of visual processing are described below, for each showing the equation that characterizes the profile data and the structure of a visual processing device that achieves visual processing that is equivalent to the visual processing device 1 provided with those profile data.

Each set of profile data is determined based on a mathematical equation that includes a computation for enhancing the values calculated from the input signal IS and the unsharp signal US. Here, this computation for enhancing is a computation that is achieved by a non-linear enhancement function, for example.

Thus, with each set of profile data, it is possible to achieve enhancement that is suited for the visual characteristics of the input signal IS or enhancement that is suited for the non-linear characteristics of the device that will output the output signal OS.

(1)

<<First Profile Data>>

The first profile data are determined in accordance with a computation that includes a function for enhancing the difference between the respective transformed values that are obtained by performing a predetermined transformation with respect to the input signal IS and the unsharp signal US. By doing this, it becomes possible to enhance the respective differences after transforming the input signal IS and the unsharp signal US in separate spaces. Thus, it is possible to

achieve enhancement that is suited for the visual characteristics, for example.

Hereinafter, this will be described in more detail.

5 The values C of the elements of the first profile data (the value of the output signal OS) are expressed by $C = F2(F1(A)+F3(F1(A)-F1(B)))$ (hereinafter, this is referred to as Equation M1) using the value A of the input signal IS, the value B of the unsharp signal US, the transformation function F1, the inverse transformation function F2 of the transformation function, and an enhancement function F3.

10 Here, the transformation function F1 is a common logarithmic function. The inverse transformation function F2 is an exponential function (antilog) that functions as the inverse function of the common logarithmic function. The enhancement function F3 is any of the enhancement functions R1 to R3 explained using Fig. 49.

15 <<Equivalent Visual Processing Device 11>>

Fig. 15 shows a visual processing device 11 that is equivalent to the visual processing device 1 in which the first profile data have been registered to the two-dimensional LUT 4.

20 The visual processing device 11 is a device that outputs an output signal OS based on a computation that enhances the differences in the transformed values of the input signal IS and the unsharp signal US after the two have been subjected to a predetermined transformation. Thus, the input signal IS and the unsharp signal US are transformed to separate spaces and their respective differences are enhanced, and this
25 allows for example enhancement that is suited for the visual characteristics to be achieved.

The visual processing device 11 shown in Fig. 15 is provided with a spatial processing portion 12 that performs spatial processing on the luminance of each pixel of an original image that it has obtained as an

input signal IS and outputs an unsharp signal US, and a visual processing portion 13 that uses the input signal IS and the unsharp signal US to perform visual processing of the original image and outputs an output signal OS.

5 The spatial processing portion 12 performs the same operation as the spatial processing portion 2 of the visual processing device 1, and thus its further description is omitted.

 The visual processing portion 13 is provided with a signal space transformation portion 14 that performs transformation of the signal
10 space of the input signal IS and the unsharp signal US and outputs a transformed input signal TIS and a transformed unsharp signal TUS, a subtracting portion 17 that receives the transformed input signal TIS as a first input and the transformed unsharp signal TUS as a second input and outputs a difference signal DS of the difference between the two, an
15 enhancing portion 18 that receives the difference signal DS as input and outputs an enhanced signal TS that has been enhanced, a summing portion 19 that receives the transformed input signal TIS as a first input and the enhanced signal TS as a second input and sums the two to obtain a summed signal PS that it then outputs, and an inverse
20 transformation portion 20 that receives the summed signal PS as an input and outputs an output signal OS.

 The signal space transformation portion 14 further includes a first transformation portion 15 that receives the input signal IS as input and outputs the transformed input signal TIS, and a second
25 transformation portion 16 that receives the unsharp signal US as input and outputs the transformed unsharp signal TUS.

<<Action of the Equivalent Visual Processing Device 11>>

 The operation of the visual processing portion 13 is described in further detail below.

The first transformation portion 15 uses the transformation function F1 to transform the input signal, which has the value A, to the transformed input signal TIS, which has the value F1(A). The second transformation portion 16 uses the transformation function F1 to transform the unsharp signal US, which has the value B, to the transformed unsharp signal TUS, which has the value F1(B). The subtracting portion 17 calculates the difference between the transformed input signal TIS having the value F1(A) and the transformed unsharp signal TUS having the value F1(B) and outputs a difference signal DS having the value $F1(A) - F1(B)$. The enhancing portion 18 uses the enhancement function F3 to output an enhanced signal TS having a value $F3(F1(A) - F1(B))$ from the difference signal DS of the value $F1(A) - F1(B)$. The summing portion 19 takes the sum of the transformed input signal TIS having the value F1(A) and the enhanced signal TS having the value $F3(F1(A) - F1(B))$ and outputs a summed signal PS that has a value $F1(A) + F3(F1(A) - F1(B))$. The inverse transformation portion 20 uses the inverse transformation function F2 to perform inverse transformation of the summed signal PS having the value $F1(A) + F3(F1(A) - F1(B))$, and outputs an output signal OS having the value $F2(F1(A) + F3(F1(A) - F1(B)))$.

It should be noted that the calculations using the transformation function F1, the inverse transformation function F2, and the enhancement function F3 each can be performed using a one-dimensional LUT for that function, or can be performed without using a LUT.

<<Effects>>

The visual processing device 11 and the visual processing device 1 provided with the first profile data attain the same visual processing effects.

(i)

Visual processing using the transformed input signal TIS and the transformed unsharp signal TUS, which were transformed to logarithmic space by the transformation function F1, is achieved. Human visual characteristics are logarithmic, and visual processing that is suited for our visual characteristics is achieved by performing processing after transforming to logarithmic space.

(ii)

With each of these visual processing devices, contrast enhancement in the logarithmic space is achieved.

The conventional visual processing device 400 shown in Fig. 48 is used for performing edge enhancement using the unsharp signal US, which generally has a small degree of blur. However, if the visual processing device 400 performs contrast enhancement using an unsharp signal US that has a large degree of blur, then bright portions in the original image are not enhanced enough and dark portions in the original image are enhanced too much, resulting in visual processing that is not suited for our visual characteristics. That is, the visual processing device 400 has a tendency for insufficient enhancement when correcting by increasing the brightness and too much enhancement when correcting by increasing the darkness.

On the other hand, if visual processing is performed using the visual processing device 1 or the visual processing device 11, it is possible to perform visual processing that is suited for our visual characteristics over a range that spans dark and light areas, and enhancement for increased brightness and enhancement for increased darkness can be performed with good balance.

(iii)

With the conventional visual processing device 400, there are

cases where the output signal OS is negative after visual processing, and fails.

On the other hand, if the value C of a particular element of the profile data found with Eq. M1 is outside of the range $0 \leq C \leq 255$, then the value of that element can be set to either 0 or 255 in order to prevent the pixel signals after correction from becoming negative and failing or becoming saturated and failing. This can be achieved regardless of the bit length for expressing the elements of the profile data.

<<Modified Examples>>

(i)

The transformation function F1 is not limited to a logarithmic function. For example, it is also possible for the transformation function F1 to achieve transformation that removes the gamma correction (for example, a gamma coefficient of "0.45") that is applied to the input signal IS, and for the inverse transformation function F2 to achieve transformation that applies the gamma correction that has been applied to the input signal IS.

The gamma correction that is applied to the input signal IS can thus be removed so as to perform processing under linear conditions. Thus, it is possible to correct optical blurring.

(ii)

With the visual processing device 11, it is also possible for the visual processing portion 13 to execute the computation of Eq. M1, without using the two-dimensional LUT 4, according to the input signal IS and the unsharp signal US. In this case, it is possible to use a one-dimensional LUT for the calculations of the functions F1 to F3.

(2)

<<Second Profile Data>>

The second profile data are determined by a computation that

includes a function for enhancing the ratio between the input signal IS and the unsharp signal US. Thus, it is for example possible to achieve visual processing that enhances the sharp component.

Further, the second profile data are determined by a computation
5 in which dynamic range compression is performed with respect to the ratio between the enhanced input signal IS and the unsharp signal US. Thus, it is for example possible to achieve visual processing in which the sharp component is enhanced while the dynamic range is compressed.

This is described in greater detail below.

10 The values C of the elements of the second profile data (the values of the output signal OS) are expressed by $C = F4(A) * F5(A/B)$ (hereinafter, this is referred to as Equation M2) using the value A of the input signal IS, the value B of the unsharp signal US, a dynamic range compression function F4, and an enhancement function F5.

15 Here, the dynamic range compression function F4 is for example a ~~monotonously~~-monotonically increasing function such as a concave power function. For example, it is expressed by $F4(x) = x^\gamma$ ($0 < \gamma < 1$). The enhancement function F5 is a power function. It is for example expressed by $F5(x) = x^\alpha$ ($0 < \alpha \leq 1$).

20 <<Equivalent Visual Processing Device 21>>

Fig. 16 shows a visual processing device 21 that is equivalent to the visual processing device 1 in which the second profile data have been registered to the two-dimensional LUT 4.

The visual processing device 21 is a device that outputs an output
25 signal OS based on a computation that enhances the ratio between the input IS and the unsharp signal US. Thus, it is for example possible to achieve visual processing for enhancing the sharp component.

The visual processing device 21 also outputs an output signal OS based on a computation in which dynamic range compression is

performed with respect to the ratio between the enhanced input signal IS and the unsharp signal US. Thus, it is for example possible to achieve visual processing in which the sharp component is enhanced while the dynamic range is compressed.

5 The visual processing device 21 shown in Fig. 16 is provided with a spatial processing portion 22 that executes spatial processing on the luminance value of each pixel of an original image that it has obtained as an input signal IS and outputs an unsharp signal US, and a visual processing portion 23 that uses the input signal IS and the unsharp
10 signal US to perform visual processing of the original image and outputs an output signal OS.

The spatial processing portion 22 performs the same operation as the spatial processing portion 2 of the visual processing device 1, and thus it will not be described further.

15 The visual processing portion 23 is provided with a dividing portion 25 that takes the input signal IS as a first input and the unsharp signal US as a second input, and divides the input signal IS by the unsharp signal US to obtain a divided signal RS that it then outputs, an enhancing portion 26 that receives the divided signal RS as input and
20 outputs an enhanced signal TS, and an output portion 27 that receives the input signal IS as a first input and the enhanced signal TS as a second input and outputs an output signal OS. The output portion 27 is provided with a DR compression portion 28 that receives the input signal IS as input and outputs a DR compressed signal DRS that has been
25 subjected to dynamic range (DR) compression, and a multiplying portion 29 that receives the DR compressed signal DRS as a first input and the enhanced signal TS as a second input and outputs an output signal OS.

<<Action of the Equivalent Visual Processing Device 21>>

The operation of the visual processing portion 23 is described in

further detail below.

The dividing portion 25 divides the input signal IS, which has the value A, by the unsharp signal US, which has the value B, and outputs a divided signal RS having the value A/B. The enhancing portion 26 uses the enhancement function F5 to output an enhanced signal TS having the value F5(A/B) from the divided signal RS having the value A/B. The DR compression portion 28 uses the dynamic range compression function F4 to output a DR compressed signal DRS having the value F4(A) from the input signal IS, whose value is A. The multiplying portion 29 multiplies the DR compressed signal DRS, whose value is F4(A), and the enhanced signal TS, whose value is F5(A/B), and outputs an output signal OS having the value $F4(A) * F5(A/B)$.

It should be noted that the calculations using the dynamic range compression function F4 and the enhancement function F5 can each be performed using a one-dimensional LUT for that function, or can be performed without using a LUT.

<<Effects>>

The visual processing device 21 and the visual processing device 1 provided with the second profile data achieve the same visual processing effects.

(i)

Conventionally, when compressing the overall dynamic range of an image, the dynamic range compression function F4 shown in Fig. 17 is used to compress the grey level from dark portions to highlights without causing saturation. That is, when L0 is the target black level to be reproduced in the image signal before compression and L1 is the maximum white level, then the dynamic range L1:L0 prior to compression is compressed to the dynamic range Q1:Q0 after compression. However, the contrast, which is the ratio of the image

signal level, is lowered to $(Q1/Q0) * (L0/L1)$ times its value due to dynamic range compression. Here, the dynamic range compression function F4 is a concave power function, for example.

However, with the visual processing device 21 and the visual
5 processing device 1 that has been provided with the second profile data, the divided signal RS having the value A/B , that is, the sharp signal enhanced by the enhancement function F5, is multiplied by the DR compressed signal DRS. The result is that local contrast is enhanced. Here, the enhancement function F5 is a power function such as that
10 shown in Fig. 18 ($F5(x) = x^\alpha$), and leads to enhancement in the bright direction when the value of the divided signal RS is greater than 1 and to enhancement in the dark direction when it is less than 1.

In general, human vision has the characteristic that an image
will be viewed at a same contrast as long as local contrast is maintained,
15 even if there is a drop in the overall contrast. Thus, with the visual processing device 21 and the visual processing device 1 that has been provided with the second profile data, it is possible to achieve visual processing with which the dynamic range is compressed but the visual contrast is not lowered.

20 (ii)

The effects of the present invention are described in further detailed below.

The dynamic range compression function F4 shall be $F4(x) = x^\gamma$
($\gamma=0.6$). The enhancement function F5 shall be $F5(x) = x^\alpha$ ($\alpha=0.4$).
25 Further, if the maximum white level of the input signal is normalized to 1, then the target black level to be reproduced shall be the value $1/300$. That is, the dynamic range of the input signal IS shall be $300:1$.

If the dynamic range of this input signal IS is compressed using the dynamic range compression function F4, then the dynamic range

after compression becomes $F4(1):F4(1/300) = 30:1$. That is, the dynamic range is compressed by 1/10 due to the dynamic range compression function F4.

On the other hand, the value C of the output signal OS is expressed by the above equation M2, where $C = (A^{0.6}) * \{(A/B)^{0.4}\}$, that is, $C = A/(B^{0.4})$. Here, in a local range the value of B is regarded as constant and thus C is proportional to A. That is, ratio of the amount of change of the value C and the amount of change of the value A is 1, and the local contrast does not change between the input signal IS and the output signal OS.

As mentioned above, human vision has the characteristic that as long as local contrast is maintained, an object will be viewed at the same contrast even if there is a drop in the overall contrast. Thus, with the visual processing device 21 and the visual processing device 1 that has been provided with the second profile data, it is possible to achieve visual processing with which the dynamic range is compressed but visually the contrast is not lowered.

It should be noted that if the power multiplier α of the enhancement function F5 shown in Fig. 18 is larger than 0.4, then it is possible to raise the visible contrast of the output signal OS over the input signal IS while performing compression of the dynamic range.

(iii)

Because the above effects can be achieved with the present invention, the invention is particularly useful in the following conditions. That is, it is possible to reproduce a high contrast image on a display having a narrow physical dynamic range without squashing the dark and light areas. It is also possible for example to display high contrast video on a television projector in a bright environment and to obtain a high contrast print using thin inks (on a printer that can print light colors

only).

<<Modified Examples>>

(i)

With the visual processing device 21, it is also possible for the
5 visual processing portion 23 to perform the calculation of Eq. M2 based
on the input signal IS and the unsharp signal US without using the
two-dimensional LUT 4. In this case, it is possible to use a
one-dimensional LUT for the calculation of each of the functions F4 and
F5.

10 (ii)

It should be noted that if the value C of a particular element of
the profile data obtained by the Eq. M2 is $C > 255$, then the value C of
that element can be regarded as 255.

15 (3)

<<Third Profile Data>>

The third profile data are determined based on a computation
that includes a function for enhancing the ratio between the input signal
IS and the unsharp signal US. Thus, it is for example possible to
20 achieve visual processing that enhances the sharp component.

This is described in further detail below.

In Eq. M2 of the second profile data, it is also possible for the
dynamic range compression function F4 to be a direct proportion
function of a proportional coefficient 1. In this case, the value C of each
25 element of the third profile data (the value of the output signal OS) is
expressed by $C = A * F5(A/B)$ (hereinafter, this is referred to as Equation
M3) using the value A of the input signal IS, the value B of the unsharp
signal US, and the enhancement function F5.

<<Equivalent Visual Processing Device 31>>

Fig. 19 shows a visual processing device 31 that is equivalent to the visual processing device 1 in which the third profile data have been registered to the two-dimensional LUT 4.

5 The visual processing device 31 is a device that outputs an output signal OS based on a computation that enhances the ratio between the input IS and the unsharp signal US. Thus, it is for example possible to achieve visual processing for enhancing the sharp component.

The visual processing device 31 shown in Fig. 19 differs from the visual processing device 21 shown in Fig. 16 in that it is not provided with the DR compression portion 28. The visual processing device 31 shown in Fig. 19 is described below, assigning the same reference numerals to and omitting description of portions that perform the same operations as those of the visual processing portion 21 shown in Fig. 16.

15 The visual processing device 31 is provided with a spatial processing portion 22 that performs spatial processing of the luminance value of each pixel of an original image that it has obtained as an input signal IS and outputs an unsharp signal US, and a visual processing portion 32 that uses the input signal IS and the unsharp signal US to perform visual processing of the original image and outputs an output signal OS.

20 The spatial processing portion 22 performs the same operation as the spatial processing portion 2 of the visual processing device 1, and thus it will not be described further.

The visual processing portion 32 is provided with a dividing portion 25 that takes an input signal IS as a first input and an unsharp signal US as a second input, and divides the input signal IS by the unsharp signal US to obtain a divided signal RS that it then outputs, an enhancing portion 26 that receives the divided signal RS as input and outputs an enhanced signal TS, and a multiplying portion 33 that

receives the input signal IS as a first input and the enhanced signal TS as a second input and outputs an output signal OS.

<<Action of the Equivalent Visual Processing Device 31>>

The operation of the visual processing portion 32 is described in
5 further detail below.

The dividing portion 25 and the enhancing portion 26 perform the same operations as described with regard to the visual processing device 21 shown in Fig. 16.

The multiplying portion 33 multiplies the input signal IS, whose
10 value is A, and the enhanced signal TS, whose value is value $F5(A/B)$, and outputs an output signal OS having the value $A * F5(A/B)$. Here, the enhancement function F5 is the same as that shown in Fig. 18.

It should be noted that the calculation using the enhancement
function F5, as described with regard to the visual processing device 21
15 shown in Fig. 16, can be performed using a one-dimensional LUT for that function, or can be performed without using a LUT.

<Effects>

The visual processing device 31 and the visual processing device
1 that has been provided with the third profile data achieve the same
20 visual processing effect.

(i)

With the enhancing portion 26, enhancement of the sharp signal
(divided signal RS), which is expressed as the ratio of the input signal IS
to the unsharp signal US, is performed, and the enhanced sharp signal
25 and the input signal IS are multiplied. Enhancement of the sharp
signal, which is expressed as the ratio of the input signal IS to the
unsharp signal US, is equivalent to calculating the difference between
the input signal IS and the unsharp signal US in logarithmic space.
That is, visual processing that is suited to the logarithmic visual

characteristics of humans is achieved.

(ii)

The amount of enhancement by the enhancement function F_5 is large if the input signal IS is large (if it is bright) and is small if the input signal IS is small (if it is dark). Also, the amount of enhancement toward increased brightness is greater than the amount of enhancement toward increased darkness. Thus, it is possible to achieve visual processing that is suited for our visual characteristics, and visual processing that is balanced and natural is achieved.

(iii)

It should be noted that if the value C of a particular element of the profile data obtained by Eq. M3 is $C > 255$, then the value C of that element can be regarded as 255.

(iv)

With the processing employing the equation M3, although compression of the dynamic range is not performed with respect to the input signal IS , local contrast can be enhanced and the dynamic range can be visually compressed and expanded.

(4)

<<Fourth Profile Data>>

The fourth profile data are determined based on a computation that includes a function for enhancing the difference between the input signal IS and the unsharp signal US in accordance with the value of the input signal IS . Due to this, it is for example possible to enhance the sharp component of the input signal IS , for example, in accordance with the value of the input signal IS . Thus, enhancement of the input signal IS can be performed suitably over a range including dark areas and light areas.

Further, the fourth profile data are determined based on a

computation that adds to the enhanced value the value that is obtained by compressing the dynamic range of the input signal IS. Thus, it is possible to enhance the sharp component of the input signal IS, for example, in accordance with the value of the input signal IS while
5 performing compression of the dynamic range.

This is described in further detail below.

The values C of the elements of the fourth profile data (the values of the output signal OS) are expressed by $C = F8(A) + F6(A) * F7(A-B)$ (hereinafter, this is referred to as Equation M4) using the value A of the
10 input signal IS, the value B of the unsharp signal US, an enhancement amount adjustment function F6, an enhancement function F7, and a dynamic range compression function F8.

Here, the enhancement amount adjustment function F6 is a function that monotonically increases with respect to the value of the
15 input signal IS. That is, when the value A of the input signal IS is small, the value of the enhancement amount adjustment function F6 also is small, and when the value A of the input signal IS is large, then the value of the enhancement amount adjustment function F6 also is large. The enhancement function F7 is any one of the enhancement functions
20 R1 to R3 that were described using Fig. 49. The dynamic range compression function F8 is the power function described using Fig. 17, and is expressed by $F8(x) = x^\gamma$ ($0 < \gamma < 1$).

<<Equivalent Visual Processing Device 41>>

Fig. 20 shows a visual processing device 41 that is equivalent to
25 the visual processing device 1 in which the fourth profile data have been registered to the two-dimensional LUT 4.

The visual processing device 41 is a device that outputs an output signal OS based on a computation for enhancing the difference between the input signal IS and the unsharp signal US in accordance with the

value of the input signal IS. Due to this, it is for example possible to enhance the sharp component of the input signal IS, for example, in accordance with the value of the input signal IS. Thus, enhancement can be suitably performed from dark areas through light areas of the
5 input signal IS.

Further, the visual processing device 41 outputs an output signal OS based on a computation that adds to the enhanced value, the value that is obtained by compressing the dynamic range of the input signal IS. Thus, it is possible to enhance the sharp component of the input signal
10 IS, for example, in accordance with the value of the input signal IS while performing compression of the dynamic range.

The visual processing device 41 shown in Fig. 20 is provided with a spatial processing portion 42 that performs spatial processing of the luminance value of each pixel of an original image that it has obtained as
15 an input signal IS and outputs an unsharp signal US, and a visual processing portion 43 that uses the input signal IS and the unsharp signal US to perform visual processing of the original image and outputs an output signal OS.

The spatial processing portion 42 performs the same operation as
20 the spatial processing portion 2 of the visual processing device 1, and thus it will not be described further.

The visual processing portion 43 is provided with a subtracting portion 44 that receives an input signal IS as a first input and an unsharp signal US as a second input and then outputs a difference signal
25 DS of the difference between the two, an enhancing portion 45 that receives the difference signal DS as an input and outputs an enhanced signal TS, an enhancement amount adjustment portion 46 that receives the input signal IS as input and outputs an enhancement amount adjusted signal IC, a multiplying portion 47 that receives the

enhancement amount adjusted signal IC as a first input and the enhanced signal TS as a second input and multiplies the enhancement amount adjusted signal IC and the enhanced signal TS to obtain a multiplied signal MS that it then outputs, and an output portion 48 that
5 receives the input signal IS as a first input and the multiplied signal MS as a second input and outputs an output signal OS. The output portion 48 is provided with a DR compression portion 49 that receives the input signal IS as input and outputs a DR compressed signal DRS that has been subjected to dynamic range (DR) compression, and a summing
10 portion 50 that receives the DR compressed signal DRS as a first input and the multiplied signal MS as a second input and outputs an output signal OS.

<<Action of the Equivalent Visual Processing Device 41>>

The operation of visual processing portion 43 is described in
15 further detail below.

The subtracting portion 44 calculates the difference between the input signal IS, which has the value A, and the unsharp signal US, which has the value B, and outputs a difference signal DS having the value A-B. The enhancing portion 45 uses the enhancement function
20 F7 to output an enhanced signal TS having the value $F7(A-B)$ from the difference signal DS, which has the value A-B. The enhancement amount adjustment portion 46 uses the enhancement amount adjustment function F6 to output an enhancement amount adjusted signal IC having the value $F6(A)$ from the input signal IS, which has the
25 value A. The multiplying portion 47 multiplies the enhancement amount adjusted signal IC, which has the value $F6(A)$, and the enhanced signal TS, which has the value $F7(A-B)$, and outputs the result as a multiplied signal MS having the value $F6(A) * F7(A-B)$. The DR compression portion 49 uses the dynamic range compression function F8

to output a DR compressed signal DRS having the value $F8(A)$ from the input signal IS, which has the value A. The summing portion 50 takes the sum of the DR compressed signal DRS and the multiplied signal MS, which has the value $F6(A) * F7(A-B)$, and outputs an output signal OS
5 having the value $F8(A) + F6(A) * F7(A-B)$.

It should be noted that the calculations using the enhancement amount adjustment function F6, the enhancement function F7, and the dynamic range compression function F8 can each be performed using a one-dimensional LUT for that function, or can be performed without
10 using a LUT.

<<Effects>>

The visual processing device 41 and the visual processing device 1 provided with the fourth profile data achieve the same visual processing effects.

15 (i)

Adjustment of the enhancement amount of the difference signal DS is performed based on the value A of the input signal IS. Thus, it is possible to perform dynamic range compression while maintaining local contrast over dark areas to light areas.

20 (ii)

The enhancement amount adjustment function F6 is a function in which the values increases monotonically, and thus it can be a function with which the amount of increase in the values of the function decreases as the value A of the input signal IS increases. In this case,
25 the value of the output signal OS is kept from becoming saturated.

(iii)

If the enhancement function F7 is the enhancement function R2 that was described using Fig. 49, then it is possible to inhibit the amount of enhancement when the absolute value of the difference signal DS is

large. Thus, the enhancement value in high-sharpness areas is kept from becoming saturated, and this allows visual processing that leads to a visually natural image to be executed.

<<Modified Examples>>

5

(i)

With the visual processing device 41, the visual processing portion 43 can also perform the computation of Eq. M4 based on the input signal IS and the unsharp signal US without using the two-dimensional LUT 4. In this case, it can also use a one-dimensional LUT in the calculations of any of the functions F6 to F8.

10

(ii)

If the enhancement function F7 is a direct proportion function of a proportion coefficient 1, then there is no particular need to provide the enhancing portion 45.

15

(iii)

It should be noted that if the value C of a particular element of the profile data found through Eq. M4 is outside the range $0 \leq C \leq 255$, then the value C of that element can be regarded as 0 or 255.

(5)

20

<Fifth Profile Data>

The fifth profile data are determined based on a computation that includes a function for enhancing the difference between the input signal IS and the unsharp signal US in accordance with the value of the input signal IS. Due to this, it is for example possible to enhance the sharp component of the input signal IS, for example, in accordance with the value of the input signal IS. Thus, enhancement of the input signal IS can be performed suitably across dark areas to light areas.

25

This is described in further detail below.

It is also possible that in Eq. M4 of the fourth profile data, the

dynamic range compression function F8 is a direct proportion function of a proportion coefficient 1. In this case, the values C of the elements of the fifth profile data (the values of the output signal OS) are expressed by $C = A + F6(A) * F7(A-B)$ (hereinafter, this is referred to as Equation M5) using the value A of the input signal IS, the value B of the unsharp signal US, the enhancement amount adjustment function F6, and the enhancement function F7.

<<Equivalent Visual Processing Device 51>>

Fig. 21 shows a visual processing device 51 that is equivalent to the visual processing device 1 in which the fifth profile data have been registered to the two-dimensional LUT 4.

The visual processing device 51 is a device that outputs an output signal OS based on a computation for enhancing the difference between the input signal IS and the unsharp signal US in accordance with the value of the input signal IS. Due to this, it is for example possible to enhance the sharp component of the input signal IS, for example, in accordance with the value of the input signal IS. Thus, enhancement of the input signal IS can be suitably performed over a range that spans dark areas and light areas.

The visual processing device 51 shown in Fig. 21 differs from the visual processing device 41 shown in Fig. 20 in that it is not provided with the DR compression portion 49. The visual processing device 51 shown in Fig. 21 is described below, assigning the same reference numerals to portions that perform the same operations as those of the visual processing portion 41 shown in Fig. 20, and detailed description thereof is omitted.

The visual processing device 51 is provided with a spatial processing portion 42 that executes spatial processing of the brightness value of each pixel of an original image that it has obtained as an input

signal IS and outputs the result as an unsharp signal US, and a visual processing portion 52 that uses the input signal IS and the unsharp signal US to perform visual processing of the original image and outputs the result as an output signal OS.

5 The spatial processing portion 42 performs the same operation as the spatial processing portion 2 of the visual processing device 1, and thus it will not be described further.

 The visual processing portion 52 is provided with a subtracting portion 44 that receives an input signal IS as a first input and an unsharp signal US as a second input and then outputs a difference signal DS of the difference between the two, an enhancing portion 45 that receives the difference signal DS as input and outputs an enhanced signal TS, an enhancement amount adjustment portion 46 that receives the input signal IS as input and outputs an enhancement amount adjusted signal IC, a multiplying portion 47 that receives the enhancement amount adjusted signal IC as a first input and the enhanced signal TS as a second input and multiplies the enhancement amount adjusted signal IC and the enhanced signal TS to obtain a multiplied signal MS that it then outputs, and a summing portion 53 that receives the input signal IS as a first input and the multiplied signal MS as a second input and outputs an output signal OS.

10

20

<<Action of the Equivalent Visual Processing Device 51>>

 The operation of the visual processing portion 52 is described in further detail below.

25 The subtracting portion 44, the enhancing portion 45, the enhancement amount adjustment portion 46, and the multiplying portion 47 perform the same operations as those described with regard to the visual processing device 41 shown in Fig. 20.

 The summing portion 53 takes the sum of the input signal IS,

which has the value A, and the multiplied signal MS, which has the value $F6(A) * F7(A-B)$, and outputs an output signal OS having the value $A + F6(A) * F7(A-B)$.

5 It should be noted that as described with respect to the visual processing device 41 shown in Fig. 20, the calculations using the enhancement amount adjustment function F6 and the enhancement function F7 can each be performed using a one-dimensional LUT for that function, or can be performed without using a LUT.

<<Effects>>

10 The visual processing device 51 and the visual processing device 1 provided with the fifth profile data achieve the same visual processing effects. Moreover, they achieve substantially the same visual processing effects as those attained by the visual processing device 41 and the visual processing device 1 provided with the fourth profile data.

15 (i)

The adjustment of the enhancement amount of the difference signal DS is performed based on the value A of the input signal IS. Thus, it is possible to attain a uniform amount of contrast enhancement from dark areas up to light areas.

20 <<Modified Examples>>

(i)

If the enhancement function F7 is a direct proportion function of a proportion coefficient 1, then it is not particularly necessary to provide the enhancing portion 45.

25 (ii)

It should be noted that if the value C of a particular element of the profile data found through Eq. M5 is outside the range $0 \leq C \leq 255$, then the value C of that element can be taken as 0 or 255.

(6)

<Sixth Profile Data>>

The sixth profile data are determined based on a computation that corrects the gradation of a value that is obtained by adding the value of the input signal IS to a value obtained by enhancing the difference between the input signal IS and the unsharp signal US. Thus, it is for example possible to achieve visual processing in which gradation correction is performed with respect to an input signal IS whose sharp component has been enhanced.

This is described in further detail below.

The values C of the elements of the sixth profile data (the values of the output signal OS) are expressed by $C = F10(A + F9(A-B))$ (hereinafter, this is referred to as Equation M6) using the value A of the input signal IS, the value B of the unsharp signal US, an enhancement function F9, and a gradation correction function F10.

Here, the enhancement function F9 is any one of the enhancement functions R1 to R3 that were described using Fig. 49. The gradation correction function F10 is a function that is used in ordinary gradation correction, and for example is a gamma correction function, an S-shaped gradation correction function, or an inverted S-shaped gradation correction function.

<<Equivalent Visual Processing Device 61>>

Fig. 22 shows a visual processing device 61 that is equivalent to the visual processing device 1 in which the sixth profile data have been registered to the two-dimensional LUT 4.

The visual processing device 61 is a device that outputs an output signal OS based on a computation that corrects the gradation of the value obtained by adding the value of the input signal IS to a value that is obtained by enhancing the difference between the input signal IS and the unsharp signal US. Thus, it is for example possible to achieve

visual processing in which gradation correction is performed with respect to an input signal IS whose sharp component has been enhanced.

The visual processing device 61 shown in Fig. 22 is provided with a spatial processing portion 62 that performs spatial processing of the luminance value of each pixel of an original image that it has obtained as an input signal IS and outputs an unsharp signal US, and a visual processing portion 63 that uses the input signal IS and the unsharp signal US to perform visual processing of the original image and outputs an output signal OS.

10 The spatial processing portion 62 performs the same operation as the spatial processing portion 2 of the visual processing device 1, and thus it will not be described further.

15 The visual processing portion 63 is provided with a subtracting portion 64 that receives an input signal IS as a first input and an unsharp signal US as a second input and then outputs a difference signal DS of the difference between the two, an enhancing portion 65 that receives the difference signal DS as input and outputs an enhanced signal TS that has been enhanced, a summing portion 66 that receives the input signal IS as a first input and the enhanced signal TS as a second input and outputs a summed signal PS that is the sum of the two, and a gradation correction portion 67 that receives the summed signal PS as input and outputs an output signal OS.

<<Action of the Equivalent Visual Processing Device 61>>

25 The operation of the visual processing portion 63 is described in further detail below.

The subtracting portion 64 calculates the difference between the input signal IS, which has the value A, and the unsharp signal US, which has the signal B, and outputs a difference signal DS having the value A-B. The enhancing portion 65 uses the enhancement function

F9 to output an enhanced signal TS having the value $F9(A-B)$ from the difference signal DS, which has the value $A-B$. The summing portion 66 takes the sum of the input signal IS, which has the value A, and the enhanced signal TS, which has the value $F9(A-B)$, and outputs a
5 summed signal PS having the value $A + F9(A-B)$. The gradation correction portion 67 uses the gradation correction function F10 to output an output signal OS having the value $F10(A + F9(A-B))$ from the summed signal PS, which has the value $A + F9(A-B)$.

It should be noted that the calculations using the enhancement
10 function F9 and the gradation correction function F10 can each be performed using a one-dimensional LUT for that function, or can be performed without using a LUT.

<<Effects>>

The visual processing device 61 and the visual processing device
15 1 furnished with the sixth profile data achieve the same visual processing effects.

(i)

The difference signal DS is enhanced by the enhancement function F9 and is added to the input signal IS. Thus, it becomes
20 possible to enhance the contrast of the input signal IS. Moreover, the gradation correction portion 67 corrects the gradation of the summed signal PS. Thus, it is for example possible to further enhance the contrast at intermediate tones, which frequently appear in original images. It is also possible to brighten the entire summed signal PS, for
25 example. Thus, spatial processing and gradation processing can be simultaneously achieved together.

<<Modified Examples>>

(i)

With the visual processing device 61, the visual processing

portion 63 can also perform the computation of Eq. M6 based on the input signal IS and the unsharp signal US without using the two-dimensional LUT 4. In this case, it is also possible to use a one-dimensional LUT for each of the calculations of the functions F9 and F10.

(ii)

It should be noted that if the value C of a particular element of the profile data found through Eq. M6 is outside the range $0 \leq C \leq 255$, then the value C of that element can be regarded as 0 or 255.

(7)

<<Seventh Profile Data>>

The seventh profile data are determined based on a computation that adds a value that is obtained by correcting the gradation of the input signal IS to a value that is obtained by enhancing the difference between the input signal IS and the unsharp signal US. Here, enhancement of the sharp component and gradation correction of the input signal IS are performed independently. Thus, it is possible to perform a fixed enhancement of the sharp component, regardless of the amount of gradation correction of the input signal IS.

This is described in further detail below.

The values C of the elements of the seventh profile data (the values of the output signal OS) are expressed by $C = F12(A) + F11(A-B)$ (hereinafter, this is referred to as Equation M7) using the value A of the input signal IS, the value B of the unsharp signal US, an enhancement function F11, and a gradation correction function F12.

Here, the enhancement function F11 is any one of the enhancement functions R1 to R3 described using Fig. 49. The gradation correction function F12 is for example a gamma correction function, an S-shaped gradation correction function, or an inverted S-shaped

gradation correction function.

<<Equivalent Visual Processing Device 71>>

Fig. 23 shows a visual processing device 71 that is equivalent to the visual processing device 1 in which the seventh profile data have
5 been registered to the two-dimensional LUT 4.

The visual processing device 71 is a device that outputs an output signal OS based on a computation that adds a value that is obtained by correcting the gradation of the input signal IS to a value that is obtained by enhancing the difference between the input signal IS and the unsharp
10 signal US. Here, enhancement of the sharp component and gradation correction of the input signal IS are performed independently. Thus, it is possible to perform a fixed enhancement of the sharp component, regardless of the amount of gradation correction of the input signal IS.

The visual processing device 71 shown in Fig. 23 is provided with
15 a spatial processing portion 72 that performs spatial processing of the luminance value of each pixel of an original image that it has obtained as an input signal IS and outputs an unsharp signal US, and a visual processing portion 73 that uses the input signal IS and the unsharp signal US to perform visual processing of the original image and outputs
20 an output signal OS.

The spatial processing portion 72 performs the same operation as the spatial processing portion 2 of the visual processing device 1, and thus it will not be described further.

The visual processing portion 73 is provided with a subtracting
25 portion 74 that receives the input signal IS as a first input and the unsharp signal US as a second input and then outputs a difference signal DS of the difference between the two, an enhancing portion 75 that receives the difference signal DS as input and outputs an enhanced signal TS that has been enhanced, a gradation correction portion 76 that

receives the input signal IS as input and outputs a gradation corrected signal GC whose gradation has been corrected, and a summing portion 77 that receives the gradation corrected signal GC as a first input and the enhanced signal TS as a second input and outputs an output signal OS.

<<Action of the Equivalent Visual Processing Device 71>>

The operation of the visual processing portion 73 is described in further detail below.

The subtracting portion 74 calculates the difference between the input signal IS, which has the value A, and the unsharp signal US, which has the signal B, and outputs a difference signal DS having the value $A-B$. The enhancing portion 75 uses the enhancement function F11 to output an enhanced signal TS having the value $F11(A-B)$ from the difference signal DS, which has the value $A-B$. The gradation correction portion 76 uses the gradation correction function F12 to output a gradation corrected signal GC having the value $F12(A)$ from the input signal IS having the value A. The summing portion 77 takes the sum of the gradation corrected signal GC, which has the value $F12(A)$, and the enhanced signal TS, which has the value $F11(A-B)$, and outputs an output signal OS having the value $F12(A) + F11(A-B)$.

It should be noted that the calculations using the enhancement function F11 and the gradation correction function F12 can each be performed using a one-dimensional LUT for that function, or can be performed without using a LUT.

<<Effects>>

The visual processing device 71 and the visual processing device 1 furnished with the seventh profile data achieve the same visual processing effects.

(i)

After the input signal IS has been subjected to gradation correction by the gradation correction portion 76, it is added to the enhanced signal TS. Thus, by adding that input signal IS to the enhanced signal TS, it is possible to emphasize local contrast even in regions where there has been little change in the gradation by the gradation correction function F12, that is, regions in which the contrast is lowered.

<<Modified Examples>>

(i)

With the visual processing device 71, the visual processing portion 73 can also perform the computation of Eq. M7 based on the input signal IS and the unsharp signal US without using the two-dimensional LUT 4. In this case, it is also possible to use a one-dimensional LUT in the calculations of the functions F11 and F12.

(ii)

It should be noted that if the value C of a particular element of the profile data found through Eq. M7 is outside the range $0 \leq C \leq 255$, then the value C of that element can be regarded as 0 or 255.

(8)

<<Modified Examples of the First through Seventh Profile Data>>

(i)

In (1) through (7) above, each element of the first through seventh profile data was described as storing a value that has been calculated based on an equation M1 through M7. It was also explained that the value of an element in the profile data that has been calculated by an equation M1 through M7 can be clipped if the value is outside of the range of values that can be stored as profile data.

Moreover, some of the values of the profile data can be any value.

For example, if the value of the input signal IS is large but the value of the unsharp signal US is small, such as small bright areas in a dark nighttime setting (such as areas of neon in a nighttime setting), then the value of the input signal IS that has been subjected to visual processing

5 will have little effect on the picture quality. Thus, for portions where the value after visual processing will have little effect on the picture quality, the values stored in the profile data can be approximate values of the value calculated by the equations M1 through M7, or can be arbitrary values.

10 Even if the values stored in the profile data are approximate values of the value calculated by the equations M1 through M7, or are arbitrary values, it is preferable that the values stored for the same values of the input signal IS and the unsharp signal US maintain the monotonically increasing, or monotonically decreasing, relationship with

15 respect to the values of the input signal IS and the unsharp signal US. In the profile data created based on the equations M1 to M7, the values stored by the profile data with respect to the same values for the input signal IS and the unsharp signal US show an overview of the characteristics of the profile data. Thus, to maintain the characteristics

20 of the two-dimensional LUT, it is preferable that the above relationship is maintained when tuning the profile data.

[Second Embodiment]

A visual processing device 600 serving as a second embodiment of

25 the present invention is described using Figs. 24 through 39.

The visual processing device 600 is a visual processing device for performing visual processing of an image signal (input signal IS) and outputting a visually processed image (output signal OS), and it performs visual processing that is in accordance with the environment in

which a display device (not shown) for displaying the output signal OS is located (hereinafter, this is referred to as the display environment).

More specifically, the visual processing device 600 is a device that fixes drops in the “visual contrast” of the display image due to the effect
5 of ambient light of the display environment by performing visual processing that utilizes our visual characteristics.

The visual processing device 600, together with a device that performs color processing of an image signal, constitutes an image processing device in a machine that handles images, such as a computer,
10 a television, a digital camera, a portable telephone, a PDA, a printer, or a scanner.

<Visual Processing Device 600>

Fig. 24 shows the basic structure of the visual processing device 600.

15 The visual processing device 600 comprises a target contrast transformation portion 601, a transformed signal processing portion 602, an actual contrast transformation portion 603, a target contrast setting portion 604, and an actual contrast setting portion 605.

The target contrast transformation portion 601 receives the input
20 signal IS as a first input and a target contrast C1 that has been set by the target contrast setting portion 604 as a second input, and outputs a target contrast signal JS. It should be noted that the target contrast C1 will be defined later.

The transformed signal processing portion 602 receives the target
25 contrast signal JS as a first input, the target contrast C1 as a second input, and the actual contrast C2 that has been set by the actual contrast setting portion 605 as a third input, and outputs a visually processed signal KS, which is the target contrast signal JS after being subjected to visual processing. It should be noted that the actual

contrast C2 will be defined later.

The actual contrast transformation portion 603 receives the visually processed signal KS as a first input and the actual contrast C2 as a second input, and outputs an output signal OS.

5 The user is allowed to set the values of the target contrast C1 and the actual contrast C2 with the target contrast setting portion 604 and the actual contrast setting portion 605 via an input interface, for example.

These portions are described in greater detail below.

10 <Target Contrast Transformation Portion 601>

The target contrast transformation portion 601 transforms the input signal IS that has been input to the visual processing portion 600 into a target contrast signal JS that is suited for contrast expression. Here, the input signal IS is expressed by a gradation in which the
15 luminance of the image that has been input to the visual processing portion 600 is from [0.1 to 1.0].

The target contrast transformation portion 601 uses a target contrast C1 (value [m]) to transform the input signal IS (value [P]) through “Eq. M20” and outputs the target contrast signal JS (value [A]).
20 Here, Eq. M20 is $A = \{(m-1)/m\} * P + 1/m$.

The value [m] of the target contrast C1 is set as the contrast value at which the displayed image that is displayed by the display device can be seen at the best contrast.

Here, the contrast value is a value that is expressed as the
25 brightness ratio of the white level to the black level of the image, and indicates the luminance value of the white level in a case where the black level has been set to 1 (black level : white level = 1:m).

The value [m] of the target contrast C1 is preferably set to approximately 100 to 1000 (black level : white level = 1:100 to 1:1000),

but this can also be determined based on the brightness ratio of the white level to the black level that can be displayed by the display device.

Transformation by Equation M20 is described in further detail using Fig. 25. Fig. 25 is a graph that shows the relationship between the value of the input signal IS (horizontal axis) and the value of the target contrast signal JS (vertical axis). As shown in Fig. 25, an input signal IS whose value is in the range of [0.0 to 1.0] is transformed into a target contrast signal JS having a value in the range of [1/m to 1.0] by the target contrast transformation portion 601.

<Transformed Signal Processing Portion 602>

Using Fig. 24, the transformed signal processing portion 602 is described in greater detail below.

The transformed signal processing portion 602 compresses the dynamic range while maintaining local contrast in the target contrast signal JS that is input, and outputs a visually processed signal KS. More specifically, the transformed signal processing portion 602 has the same structure, action, and effect as if in the visual processing device 21 described in the first embodiment the input signal IS (see Fig. 16) is regarded as the target contrast signal JS and the output signal OS (see Fig. 16) is regarded as the visually processed signal KS.

The transformed signal processing portion 602 outputs the visually processed signal KS based on a computation that enhances the ratio between the target contrast signal JS and the unsharp signal US. Thus, it is for example possible to achieve the visual processing for enhancing the sharp component.

Further, the transformed signal processing portion 602 outputs the visually processed signal KS based on a computation for compressing the dynamic range of the ratio between the target contrast signal JS that has been enhanced and the unsharp signal US. Thus, it is possible to

achieve visual processing in which the sharp component is enhanced while the dynamic range is compressed, for example.

<<Structure of the Transformed Signal Processing Portion
602>>

5 The transformed signal processing portion 602 is provided with a spatial processing portion 622 that performs spatial processing on the luminance value of each pixel in the target contrast signal JS and outputs an unsharp signal US, and a visual processing portion 623 that uses the target contrast signal JS and the unsharp signal US to perform
10 visual processing of the target contrast signal JS and outputs a visually processed signal KS.

The spatial processing portion 622 performs the same operation as the spatial processing portion 2 of the visual processing device 1 (see Fig. 1), and thus detailed description thereof is omitted.

15 The visual processing portion 623 is provided with a dividing portion 625, an enhancing portion 626, and an output portion 627 that has a DR compression portion 628 and a multiplying portion 629.

The dividing portion 625 receives the target contrast signal JS as a first input and the unsharp signal US as a second input and divides
20 the target contrast signal JS by the unsharp signal US to obtain a divided signal RS that it then outputs. The enhancing portion 626 receives the divided signal RS as a first input, the target contrast C1 as a second input, and the actual contrast C2 as a third input, and outputs an enhanced signal TS.

25 The output portion 627 receives the target contrast signal JS as a first input, the enhanced signal TS as a second input, the target contrast C1 as a third input, and the actual contrast C2 as a fourth input, and outputs a visually processed signal KS. The DR compression portion 628 receives the target contrast signal JS as a first input, the target

contrast C1 as a second input, and the actual contrast C2 as a third input, and outputs a DR compressed signal DRS whose dynamic range (DR) has been compressed. The multiplying portion 629 receives the DR compressed signal DRS as a first input and the enhanced signal TS
5 as a second input, and outputs the visually processed signal KS.

<<Action of the Transformed Signal Processing Portion 602>>

The transformed signal processing portion 602 uses the target contrast C1 (value [m]) and the actual contrast C2 (value [n]) to transform the target contrast signal JS (value [A]) through "Eq. M2" and
10 outputs the result as a visually processed signal KS (value [C]). Here, Eq. M2 is expressed as $C = F4(A) * F5(A/B)$ using the dynamic range compression function F4 and the enhancement function F5. It should be noted that the value [B] is the value of the unsharp signal US obtained by subjecting the target contrast signal JS to spatial processing.

15 The dynamic range compression function F4 is a "power function" that is a concave ~~monotonously~~ monotonically increasing function, and is expressed by $F4(x) = x^\gamma$. The exponent γ of the dynamic range compression function F4 is expressed using normal logarithms by $\gamma = \log(n)/\log(m)$. The enhancement function F5 is a power function, and
20 is expressed by $F5(x) = x^{(1-\gamma)}$.

The relationship between Eq. M2 and the operations of the various portions of the transformed signal processing portion 602 is described in further detail below.

The spatial processing portion 622 performs spatial processing
25 with respect to the target contrast signal JS, which has the value [A], and outputs the result as an unsharp signal US having the value [B].

The dividing portion 625 divides the target contrast signal JS, which has the value [A], by the unsharp signal US, which has the value [B], and outputs the result as the divided signal RS, which has the value

[A/B]. The enhancing portion 626 uses the enhancement function F5 to obtain an enhanced signal TS having the value $[F5(A/B)]$ from the divided signal RS, which has the value $[A/B]$, and outputs this enhanced signal TS. The DR compression portion 628 uses the dynamic range
5 compression function F4 to obtain a DR compressed signal DRS having the value $[F4(A)]$ from the target contrast signal JS, which has the value $[A]$, and outputs the DR compressed signal DRS. The multiplying portion 629 multiplies the DR compressed signal DRS, which has the value $[F4(A)]$, by the enhanced signal TS, which has the value $[F5(A/B)]$,
10 and outputs the result as a visually processed signal KS having the value $[F4(A) * F5(A/B)]$.

It should be noted that the calculations using the dynamic range compression function F4 and the enhancement function F5 can each be performed using a one-dimensional LUT for that function, or can be
15 performed without using a LUT.

<<Effect of the Transformed Signal Processing Portion 602>>

The visual dynamic range in the visually processed signal KS is determined by the value of the dynamic range compression function F4.

The transformation by Eq. M2 is described in more specific detail
20 using Fig. 26. Fig. 26 is a graph showing the relationship between the value of the target contrast signal JS (horizontal axis) and the value obtained by applying the dynamic range compression function F4 to the target contrast signal JS (vertical axis). As shown in Fig. 26, the dynamic range of the target contrast signal JS is compressed by the
25 dynamic range compression function F4. More specifically, a target contrast signal JS in the value range of $[1/m \text{ to } 1.0]$ is transformed by the dynamic range compression function F4 to a value range of $[1/n \text{ to } 1.0]$. As a result, the viewable dynamic range of the visually processed signal KS is compressed to $1/n$ (minimum value : maximum value = $1:n$).

The actual contrast C2 shall be described here. The value [n] of the actual contrast C2 is set as the viewable contrast value of the displayed image under the circumstances of the ambient light of the display environment. That is, the value [n] of the actual contrast C2
5 can be determined to be the value obtained by lowering the value [m] of the target contrast C1 by an amount that corresponds to the impact of the luminance of the ambient light of the display environment.

As the result of using the value [n] of the actual contrast C2 that has been set in this way, the dynamic range of the target contrast signal
10 JS following from Eq. M2 is compressed to between 1:m and 1:n. It should be noted that here “dynamic range” means the ratio between the minimum value and the maximum value of the signal.

On the other hand, the change in the local contrast in the visually processed signal KS is expressed as the ratio of the change
15 amount before and after transformation between the value [A] of the target contrast signal JS and the value [C] of the visually processed signal KS. Here, the value [B] of the unsharp signal US in a local, that is, narrow range is regarded as constant. Thus, the ratio between the amount of change in the value [C] and the amount of change in the value
20 [A] in Eq. M2 is 1, meaning that the local contrast does not change between the target contrast signal JS and the visually processed signal KS.

Human vision has the characteristic that as long as local contrast is maintained, an image will be viewed at the same contrast even if there
25 is a drop in the overall contrast. Thus, with the transformed signal processing portion 602, it is possible to achieve visual processing with which the dynamic range of the target contrast signal JS is compressed but the viewable contrast is not lowered.

<Actual Contrast Transformation Portion 603>

The actual contrast transformation portion 603 is described in detail using Fig. 24.

5 The actual contrast transformation portion 603 transforms the visually processed signal KS into image data of a range that can be input to a display device (not shown). The image data of a range that can be input to a display device are image data in which the luminance values of the image are expressed in a gray scale value range of [0.0 to 1.0].

The actual contrast transformation portion 603 uses the actual contrast C2 (value [n]) to transform the visually processed signal KS
10 (value [C]) with "Equation M21," and outputs the result as an output signal OS (value [Q]). Here, Eq. M21 is $Q = \{n/(n-1)\} * C - \{1/(n-1)\}$.

This transformation following from Eq. M21 is described in greater detail using Fig. 27. Fig. 27 is a graph showing the relationship between the value of the visually processed signal KS (horizontal axis)
15 and the value of the output signal OS (vertical axis). As shown in Fig. 27, the actual contrast transformation portion 603 transforms a visually processed signal KS, which is in the range of [1/n to 1.0], into an output signal OS that has a range of [0.0 to 1.0]. Here, the value of the output signal OS decreases with respect to the value of the visually processed
20 signal KS. The amount of this decrease corresponds to the impact of the ambient light on the luminance values of the display image.

It should be noted that if a visually processed signal KS having a value less than [1/n] is input, then the actual contrast transformation portion 603 transforms the output signal OS to the value [0]. Further, if
25 a visually processed signal KS having a value greater than [1] is input, then the actual contrast transformation portion 603 transforms the output signal OS to the value [1].

<Effects of the Visual Processing Device 600>

The visual processing device 600 attains the same effects as the

visual processing device 21 described in the first embodiment. Those characteristic effects of the visual processing device 600 are discussed below.

(i)

5 When there is ambient light in the display environment in which the visual processing device 600 displays the output signal OS, the ambient light affects how the output signal OS is viewed. However, the output signal OS is a signal in which processing to correct the impact of ambient light has been executed by the actual contrast transformation
10 portion 603. That is, in a display environment where there is ambient light, the output signal OS that is displayed by the display device is viewed as a display image having the characteristics of the visually processed signal KS.

 As for the characteristics of the visually processed signal KS, like
15 for example the output signal OS of the visual processing device 21 described in the first embodiment (see Fig. 16), the local contrast is maintained while compressing the dynamic range of the entire image. That is, the visually processed signal KS is a signal in which the target contrast C1 at which locally the display image is displayed most suitably
20 is maintained while the dynamic range is compressed to a dynamic range that can be displayed in the presence of the ambient light (this corresponds to the actual contrast C2).

 Thus, with the visual processing device 600, it is possible to correct the contrast, which drops due to the presence of ambient light,
25 while maintaining the visual contrast through processing that exploits the viewing characteristics.

<Visual Processing Method>

 The visual processing method for achieving the same effects as the visual processing device 600 is described below using Fig. 28. It

should be noted that the specific processing of each step is the same as that in the visual processing device 600, and thus description thereof will be omitted.

With the visual processing method shown in Fig. 28, first the
5 target contrast C1 that has been set and the actual contrast C2 are obtained (S601). Next, the target contrast C1 that has been obtained is used to transform the input signal IS (step S602), and the result is output as a target contrast signal JS. The target contrast signal JS is then subjected to spatial processing (step S603) and the result is output
10 as an unsharp signal US. The target contrast signal JS is then divided by the unsharp signal US (step S604) and the result is output as a divided signal RS. The divided signal RS is enhanced by the enhancement function F5, which is a “power function” whose exponent is determined by the target contrast C1 and the actual contrast C2 (step
15 S605), and the result is output as an enhanced signal TS. On the other hand, the dynamic range of the target contrast signal JS is compressed by the dynamic range compression function F4, which is a “power function” whose exponent is determined by the target contrast C1 and the actual contrast C2 (step S606), and the result is output as a DR
20 compressed signal DRS. Next, the enhanced signal TS output in step S605 and the DR compressed signal DRS output in step S606 are multiplied (step S607), and the result is output as a visually processed signal KS. Next, the actual contrast C2 is used to transform the visually processed signal KS (step S608), and the result is output as an
25 output signal OS. The processes of steps S602 through S608 are repeated for every pixel of the input signal IS (step S609).

The steps of the visual processing method shown in Fig. 28 can also be achieved as a visual processing program in the visual processing device 600 or another computer, for example. It is also possible for all

the processes of steps S604 to S607 to be executed at one time by performing the calculation of Eq. M2.

<Modified Examples>

The present invention is not limited to the foregoing embodiment,
5 and various modifications and improvements thereof are possible without departing from the gist of the invention.

(i) Eq. M2 – A Case in Which the Enhancement Function F5 Is Not Provided –

In the foregoing embodiment, the transformed signal processing
10 portion 602 was described as outputting a visually processed signal KS based on Eq. M2. Here, it is also possible for the transformed signal processing portion 602 to output a visually processed signal KS based only on the dynamic range enhancement function F4. In this case, it is not necessary for the transformed signal processing portion 602 of this
15 modified example to be provided with the spatial processing portion 622, the dividing portion 625, the enhancing portion 626, or the multiplying portion 629, and it is only necessary that it is provided with the DR compression portion 628.

With the transformed signal processing portion 602 of this
20 modified example, it is possible to output a visually processed signal KS that has been compressed to a dynamic range that can be displayed under the conditions of ambient light.

(ii) Enhancement Function F5 – Exponents and Other Modified Examples –

25 In the foregoing embodiment, the enhancement function F5 is a “power function” and expressed as $F5(x) = x^{(1-\gamma)}$. Here, the exponent of the enhancement function F5 can be a function of the value [A] of the target contrast signal JS or the value [B] of the unsharp signal US.

Specific Examples <<1>> to <<6>> are described below.

<<1>>

If the exponent of the enhancement function F5 is a function of the value [A] of the target contrast signal JS, and the value [A] of the target contrast signal JS is larger than the value [B] of the unsharp signal US, then the enhancement function F5 is a function that monotonically decreases. More specifically, the exponent of the enhancement function F5 is expressed as $\alpha_1(A) * (1-\gamma)$, where the function $\alpha_1(A)$ is a function that monotonically decreases with respect to the value [A] of the target contrast signal JS as shown in Fig. 29. It should be noted that the maximum value of the function $\alpha_1(A)$ is [1.0].

In this case, there is little enhancement of the local contrast of high luminance portions by the enhancement function F5. For this reason, if the luminance of a target pixel is higher than the luminance of the surrounding pixels, then the local contrast of the high luminance portion is kept from being over-enhanced. That is, the luminance of the target pixel is kept from becoming saturated at the high luminance, resulting in "blooming."

<<2>>

If the exponent of the enhancement function F5 is a function of the value [A] of the target contrast signal JS, and the value [A] of the target contrast signal JS is smaller than the value [B] of the unsharp signal US, then the enhancement function F5 is a function that monotonically increases. More specifically, the exponent of the enhancement function F5 is expressed as $\alpha_2(A) * (1-\gamma)$, where the function $\alpha_2(A)$ is a function that monotonically increases with respect to the value [A] of the target contrast signal JS is shown in Fig. 30. It should be noted that the maximum value of the function $\alpha_2(A)$ is [1.0].

In this case, there is little enhancement of the local contrast of low luminance portions by the enhancement function F5. For this

reason, if the luminance of a target pixel is lower than the luminance of the surrounding pixels, then the local contrast of the low luminance portion is kept from being over-enhanced. That is, the luminance of the target pixel is kept from being saturated at the low luminance and
5 resulting in black squashing.

<<3>>

If the exponent of the enhancement function F5 is a function of the value [A] of the target contrast signal JS, and the value [A] of the target contrast signal JS is larger than the value [B] of the unsharp
10 signal US, then the enhancement function F5 is a function that monotonically increases. More specifically, the exponent of the enhancement function F5 is expressed as $\alpha 3(A) * (1-\gamma)$, where the function $\alpha 3(A)$ is a function that monotonically increases with respect to the value [A] of the target contrast signal JS as shown in Fig. 31. It
15 should be noted that the maximum value of the function $\alpha 3(A)$ is [1.0].

In this case, there is little enhancement of the local contrast of low luminance portions by the enhancement function F5. For this reason, if the luminance of a target pixel is higher than the luminance of the surrounding pixels, then the local contrast of the low luminance
20 portion is kept from being over-enhanced. The low luminance portions in the image have a small signal level, and thus the ratio to noise is relatively high, but by performing this processing it is possible to keep the SN ratio from becoming worse.

<<4>>

25 The exponent of the enhancement function F5 is a function of the value [A] of the target contrast signal JS and the value [B] of the unsharp signal US, and monotonically decreases with respect to the absolute value of the difference between the value [A] and the value [B]. In other words, the exponent of the enhancement function F5 could be

said to be a function that increases the closer the ratio of the value [A] to the value [B] is to 1. More specifically, the exponent of the enhancement function F5 is expressed as $\alpha 4(A,B) * (1-\gamma)$, where the function $\alpha 4(A,B)$ is a function that monotonically decreases with respect to the absolute value of the value [A-B] as shown in Fig. 32.

In this case, it is possible to particularly enhance the local contrast in target pixels whose difference in brightness with respect to the surrounding pixels is small, and to inhibit the enhancement of the local contrast in target pixels whose difference in brightness with respect to the surrounding pixels is large.

<<5>>

It is also possible to set an upper limit or a lower limit to the result of the computation of the enhancement function F5 in <<1>> though <<4>> above. More specifically, if the value [F5(A/B)] is greater than a predetermined upper limit value, then the predetermined upper limit value can be adopted as the result of the computation of the enhancement function F5. Likewise, if the value [F5(A/B)] is lower than a predetermined lower limit value, then the predetermined lower limit value can be adopted as the result of the computation of the enhancement function F5.

In this case, it is possible to restrict the amount that the local contrast is enhanced by the enhancement function F5 to a suitable range, and this inhibits over- or under-enhancement of the contrast.

<<6>>

It should be noted that <<1>> through <<5>> discussed above can be similarly adopted in a case where a computation that employs the enhancement function F5 is performed in the first embodiment (for example, in <Profile Data> (2) or (3) in the first embodiment). It should be noted that in the first embodiment the value [A] is the value of the

input signal IS, and the value [B] is the value of the unsharp signal US that is obtained by spatially processing the input signal IS.

(iii) Equation M2 – Case in which Dynamic Range Compression is not Performed –

5 In the foregoing embodiment, the transformed signal processing portion 602 was described as having the same configuration as the visual processing device 21 shown in the first embodiment. Here, as a modified example of the transformed signal processing portion 602 it is possible for it to have the same configuration as the visual processing
10 device 31 shown in the first embodiment (see Fig. 19). More specifically, it is possible to achieve a modified example of the transformed signal processing portion 602 by taking the visual processing device 31 and regarding the input signal IS as the target contrast signal JS and regarding the output signal OS as the visually processed signal KS.

15 In this case, with the transformed signal processing portion 602 of this modified example, the visually processed signal KS (value [C]) is output based on “Equation M3” with respect to the target contrast signal JS (value [A]) and the unsharp signal US (value [B]). Here, Eq. M3 is expressed as $C = A * F5(A/B)$, using the enhancement function F5.

20 With the processing using Eq. M3, the dynamic range of the input signal IS is not compressed, but it is possible to enhance the local contrast. Due to the effect of enhancing the local contrast, it is possible to give the impression of a “visually” compressed or expanded dynamic range.

25 It should be noted that <Modified Examples> (ii) <<1>> to <5>> discussed above can be similarly adopted in this modified example as well. That is, in this modified example, the enhancement function F5 is a “power function” whose exponent has the same trend as a function $\alpha 1(A)$, $\alpha 2(A)$, $\alpha 3(A)$, and $\alpha 4(A,B)$ discussed in the above <Modified

Examples> (ii) <<1>> to <4>>. As discussed in the above <Modified Example> (ii) <<5>>, it is also possible to establish an upper limit or a lower limit for the result of the computation of the enhancement function F5.

5 (iv) Automatic Setting of Parameters

In the foregoing embodiment, the target contrast setting portion 604 and the actual contrast setting portion 605 were described as allowing the user to set the values of the target contrast C1 and the actual contrast C2 through an input interface, for example. It is also
10 possible for the target contrast setting portion 604 and the actual contrast setting portion 605 to automatically set the values of the target contrast C1 and the actual contrast C2.

<<1>> Display

An actual contrast setting portion 605 that automatically sets the
15 value of the actual contrast C2 will be described below with regard to a case in which the display device for displaying the output signal OS is a display such as a PDP, LCD, or CRT, and the white luminance (white level) and black luminance (black level) that can be displayed under conditions in which there is no ambient light are known already.

20 Fig. 33 shows the actual contrast setting portion 605 that automatically sets the value of the actual contrast C2. The actual contrast setting portion 605 is provided with a luminance measuring portion 605a, a memory portion 605b, and a calculation portion 605c.

The luminance measuring portion 605a is a luminance sensor
25 that measures the luminance value of the ambient light in the display environment of the display that will display the output signal OS. The memory portion 605b stores the white luminance (white level) and black luminance (black level) that can be displayed under the condition of no ambient light by the display for displaying the output signal OS. The

calculation portion 605c obtains values from the luminance measuring portion 605a and the memory portion 605b and uses these to calculate the value of the actual contrast C2.

5 An example of the calculation of the calculation portion 605c is described below. The calculation portion 605c adds the luminance value of the ambient light that it obtains from the luminance measuring portion 605a to each of the luminance value of the black level and the luminance value of the white level stored in the memory portion 605b. The calculation portion 605c then divides the result obtained by this
10 addition to the luminance value of the white level by the result obtained by this addition to the luminance value of the black level, and outputs the value that is obtained as the value [n] of the actual contrast C2. Thus, the value [n] of the actual contrast C2 indicates the contrast value that is displayed by the display in a display environment in which there
15 is ambient light.

It is also possible for the memory portion 605b shown in Fig. 33 to store the ratio of the white luminance (white level) and black luminance (black level) that can be displayed by the display under the condition of no ambient light as the value [m] of the target contrast C1.
20 In this case, the actual contrast setting portion 605 simultaneously also functions as the target contrast setting portion 604 for automatically setting the target contrast C1. It should be noted that it is also possible for the memory portion 605b to not store this ratio and instead for this ratio to be calculated by the calculation portion 605c.

25 <<2>> Projector

An actual contrast setting portion 605 that automatically sets the value of the actual contrast C2 will be described below with regard to a case in which the display device for displaying the output signal OS is a projector, for example, and the white luminance (white level) and black

luminance (black level) that can be displayed under the conditions of no ambient light depend on the distance to the screen.

Fig. 34 shows an actual contrast setting portion 605 for automatically setting the value of the actual contrast C2. The actual
5 contrast setting portion 605 is provided with a luminance measuring portion 605d and a control portion 605e.

The luminance measuring portion 605d is a luminance sensor that measures the luminance value in the display environment of the output signal OS that is displayed by the projector. The control portion
10 605e causes the projector to perform a display of the white level and the black level. It also obtains the luminance values when those levels are displayed from the luminance measuring portion 605d and calculates the value of the actual contrast C2.

An example of the operation of the control portion 605e is
15 described using Fig. 35. First, the control portion 605e operates the projector in a display environment in which ambient light is present and causes it to perform a display of the white level (step S620). The control portion 605e obtains the luminance value of the white level that has been measured from the luminance measuring portion 605d (step S621).
20 Next, the control portion 605e operates the projector in a display environment in which ambient light is present and causes it to perform a display of the black level (step S622). The control portion 605e obtains the luminance value of the black level that has been measured from the luminance measuring portion 605d (step S623). The control portion
25 605e then calculates the ratio between the luminance value of the white level and the luminance value of the black level that have been obtained, and outputs the result as the value of the actual contrast C2 (step S624). The result of this is that the value [n] of the actual contrast C2 indicates the contrast value that is displayed by the projector in a display

environment in which ambient light is present.

In the same manner as described above, it is also possible to derive the value $[m]$ of the target contrast $C1$ by calculating the ratio of the white level to the black level in a display environment in which no ambient light is present. In this case, the actual contrast setting portion 605 ends up simultaneously also achieving the function of the target contrast setting portion 604 for automatically setting the target contrast $C1$.

(v) Other Signal Space

In the foregoing embodiment, the processing in the visual processing device 600 was described as being performed with respect to the luminance of the input signal IS . Here, the present invention is not limited to being useful for only a case in which the input signal IS is represented by a $YCbCr$ color space. It is also possible for the input signal IS to be represented in YUV color space, Lab color space, Luv color space, YIQ color space, XYZ color space, or $YPbPr$ color space, for example. In the case of these, it is possible to execute the processing described in the foregoing embodiment with respect to the luminance or brightness of that color space.

Also, if the input signal IS is represented in RGB color space, then the processing by the visual processing portion 600 can also be performed independently for each RGB component. That is, processing by the target contrast transformation portion 601 is performed independently for the RGB components of the input signal IS , and the RGB components of the target contrast signal JS are output. Also, processing by the transformed signal processing portion 602 is performed independently for each of the RGB components of the target contrast signal JS , and the RGB components of the visually processed signal KS are output. Further, processing by the actual contrast transformation

portion 603 is performed independently for the RGB components of the visually processed signal KS, and the RGB components of the output signal OS are output. Here, the same value for the target contrast C1 and for the actual contrast C2 can be used to process each of the RGB components.

(vi) Color Difference Correction

The visual processing device 600 can be further provided with a color difference correcting portion in order to prevent the hue of the output signal OS from differing from the hue of the input signal IS due to the impact of the luminance component that has been processed by the transformed signal processing portion 602.

Fig. 36 shows the visual processing device 600 provided with a color difference correcting portion 608. It should be noted that the structural components that are the same as those of the visual processing device 600 shown in Fig. 24 are assigned the same reference numerals. The input signal IS shall have a YCbCr color space, in which the Y component is subjected to the same processing as described in the above embodiment. The color difference correcting portion 608 is described below.

The color difference correcting portion 608 receives the target contrast signal JS as a first input (value [Yin]), the visually processed signal KS as a second input (value [Yout]), the Cb component of the input signal IS as a third input (value [CBin]), and the Cr component of the input signal IS as a fourth input (value [CRin]), and outputs the Cb component after color difference correction as a first output (value [CBout]), and the Cr component after color difference correction as a second output (value [CRout]).

Fig. 37 shows an overview of color difference correction. The color difference correcting portion 608 has four inputs [Yin], [Yout],

[CBin], and [CRin], and by performing computations with these four inputs, obtains two outputs [CBout] and [CRout].

[CBout] and [CRout] are derived based on the following equations for correcting [CBin] and [CRin] based on the difference and the ratio
5 between [Yin] and [Yout].

[CBout] is derived based on $a1 * ([Yout] - [Yin]) * [CBin] + a2 * (1 - [Yout]/[Yin]) * [CBin] + a3 * ([Yout] - [Yin]) * [CRin] + a4 * (1 - [Yout]/[Yin]) * [CRin] + [CBin]$ (hereinafter, referred to as the CB equation).

10 [CRout] is derived based on $a5 * ([Yout] - [Yin]) * [CBin] + a6 * (1 - [Yout]/[Yin]) * [CBin] + a7 * ([Yout] - [Yin]) * [CRin] + a8 * (1 - [Yout]/[Yin]) * [CRin] + [CRin]$ (hereinafter, referred to as the CR equation).

The values that are used for the coefficients a1 to a8 in the CB
15 equation and the CR equation are determined by a calculating device outside the visual processing device 600, for example, in advance by an estimation computation that is described below.

The computation for estimating the coefficients a1 to a8 with a calculating device or the like is described below using Fig. 38.

20 First, the four inputs of [Yin], [Yout], [CBin], and [CRin] are obtained (step S630). The value of each of these inputs is data that has been prepared in advance to determine the coefficients a1 to a8. For example, [Yin], [CBin], and [CRin] can each be a value that is obtained by decimating all of the obtainable values at a predetermined interval.
25 As [Yout], it is possible to use a value that is obtained by decimation at a predetermined interval of the values that can be output when the value of [Yin] has been input to the transformed signal processing portion 602. The data that has been prepared in this manner are obtained as the four inputs.

The [Yin], [CBin], and [CRin] that are obtained are transformed into a Lab color space and the chromaticity values [Ain] and [Bin] in the transformed Lab color space are calculated (step S631).

Next, default coefficients a1 to a8 are used to perform the calculations of the “CB equation” and the “CR equation,” from these obtaining values for [CBout] and [CRout] (step S632). These obtained values and [Yout] are transformed into Lab color space, and the chromaticity values [Aout] and [Bout] in the transformed Lab color space are calculated (step S633).

Next, the chromaticity values [Ain], [Bin], [Aout], and [Bout] that have been calculated are used to perform calculation of an evaluation function (step S634), and then it is determined whether or not the value of the evaluation function is equal to or less than a predetermined threshold value. Here, the evaluation function is a function whose value is small if the hue change is small between [Ain] and [Bin] and between [Aout] and [Bout], and for example it is the squared-sum of the deviation between each of these components. More specifically, it can be $([Ain]-[Aout])^2 + ([Bin]-[Bout])^2$.

If the value of the evaluation function is greater than the predetermined threshold value (step S635), then the coefficients a1 to a8 are corrected (step S636), and the computations of the steps S632 to S635 are repeated using the new coefficients.

If the value of the evaluation function is less than the predetermined threshold value (step S635), then the coefficients a1 to a8 that have been used for calculating the evaluation function are output as the results of the estimation computation (step S637).

It should be noted that in the estimation calculation, any one of the combinations of the four inputs [Yin], [Yout], [CBin], and [CRin], which are prepared in advance, can be used to estimate the coefficients

a1 through a8, but it is also possible to use a plurality of combinations to perform the above processing and then output the coefficients a1 through a8 having the smallest evaluation function as the outcome of the estimation calculation.

5 [Modified Examples of Color Difference Correction]

<<1>>

With the color difference correcting portion 608, [Yin] is taken as the value of the target contrast signal JS, [Yout] is taken as the value of the visually processed signal KS, [CBin] is taken as the value of the Cb component of the input signal IS, [CRin] is taken as the value of the Cr component of the input signal IS, [CBout] is taken as the value of the Cb component of the output signal OS, and [CRout] is taken as the value of the Cr component of the output signal OS. Here, it is also possible for [Yin], [Yout], [CBin], [CRin], [CBout], and [CRout] to represent other signal values.

For example, if the input signal IS is in RGB color space, then the target contrast transformation portion 601 (see Fig. 24) performs processing with respect to each of these components of the input signal IS. In this case, the processed RGB color space signal can be transformed into a YCbCr color space signal in which [Yin] is the value of the Y component, [CBin] is the value for the Cb component, and [CRin] is the value of the Cr component.

Further, if the output signal OS is a signal in RGB color space, then derived values for [Yout], [CBout], and [CRout] are transformed into an RGB color space, and each of these components is transformed by the actual contrast transformation portion 603 to produce the output signal OS.

<<2>>

It is also possible for the color difference correcting portion 608 to

use the ratio of the signal values before and after processing by the transformed signal processing portion 602 to correct each of the R, G, and B components that are input to the color difference correcting portion 608.

5 A modified example of the structure of the visual processing device 600 is described using Fig. 39. It should be noted that portions that attain substantially the same function as those of the visual processing device 600 shown in Fig. 36 are assigned identical reference numerals and shall not be described here. A feature of the
10 configuration of the visual processing device 600 of this modified example is that it is provided with a luminance signal creation portion 610.

Each component of the input signal IS, which is a signal in RGB color space, is transformed to a target contrast signal JS, which is a
15 signal in RGB color space, in the target contrast transformation portion 601. This process is described in detail above and thus will not be described here. Here, [Rin], [Gin], and [Bin] serve as the values of the respective components of the target contrast signal JS.

The luminance signal creation portion 610 creates a luminance
20 signal having the value [Yin] from the various components of the target contrast signal JS. The luminance signal is found by taking the sum of the values of the R, G, and B components in a particular proportion. For example, the value [Yin] can be found by the equation $[Yin] = 0.299*[Rin] + 0.587*[Gin] + 0.114*[Bin]$.

25 The transformed signal processing portion 602 processes the luminance signal having the value [Yin] and outputs the result as a visually processed signal KS having the value [Yout]. More specifically, this processing is the same as the processing by the transformed signal processing portion 602 (see Fig. 36), which outputs the visually processed

signal KS from the target contrast signal JS, and thus will not be described here further.

5 The color difference correcting portion 608 uses the luminance signal (value [Yin]), the visually processed signal KS (value [Yout]), and the target contrast signal JS (value [Rin], [Gin], and [Bin]) to output a color difference correction signal (value [Rout], [Gout], [Bout]), which is a signal in RGB color space.

 More specifically, the color difference correcting portion 608 calculates the value [Yin] to value [Yout] ratio (the value $[[Yout]/[Yin]]$).
10 The calculated ratio is multiplied to each component of the target contrast signal JS (values [Rin], [Gin], and [Bin]) as a color difference correction coefficient. Accordingly, a color difference correction signal (values [Rout], [Gout], and [Bout]) is output.

 The actual contrast transformation portion 603 transforms each
15 component of the color difference correction signal, which is a signal in RGB color space, transforming it into an output signal OS, which is a signal in RGB color space. The details for this processing have been discussed before, and this will not be described here.

 With the visual processing device 600 of this modified example,
20 the transformed signal processing portion 602 performs processing only with respect to the luminance signal, and thus it is not necessary to process each RGB component. Thus, the visual processing burden per input signal IS in RGB color space is reduced.

 <<3>>

25 The “CB equation” and “CR equation” are only examples, and other equations can also be used.

 (vii) Visual Processing Portion 623

 The visual processing portion 623 shown in Fig. 24 can also be constituted by a two-dimensional LUT.

In this case, the two-dimensional LUT stores the values of the visually processed signal KS with respect to the values of the target contrast signal JS and the values of the unsharp signal US. More specifically, the values of the visual processing signal KS are determined
5 based on "Eq. M2," which was described in [First Embodiment] <Profile Data> (2) <<Second Profile Data>>. It should be noted that in the "Eq. M2" the value of the target contrast signal JS serves as the A value and the value of the unsharp signal US is used as the value B.

The visual processing device 600 is provided with a plurality of
10 such two-dimensional LUTs in a memory device (not shown). Here, the memory device can be internally provided in the visual processing device 600, or it can be connected to an external portion thereof through a wired or wireless connection. Each two-dimensional LUT stored on the memory device is correlated to the values of the target contrast C1 and
15 the values of the actual contrast C2. That is, the same computation as that described above in [Second Embodiment] <Transformed Signal Processing Portion 602> <<Action of Transformation Signal Processing Portion 602>> is performed with respect to each combination of the value of the target contrast C1 and the value of the actual contrast C2, and
20 stores the result as a two-dimensional LUT.

When the visual processing portion 623 obtains the values of the target contrast C1 and the actual contrast C2, the two-dimensional LUT that corresponds to those values that have been obtained from among the two-dimensional LUTs stored on the memory device is read out. Then,
25 the visual processing portion 623 uses the two-dimensional LUT that has been read out and performs visual processing. More specifically, the visual processing portion 623 obtains the value of the target contrast signal JS and the value of the unsharp signal US, and reads the value of the visually processed signal KS corresponding to those obtained values

from the two-dimensional LUT and outputs the visually processed signal KS.

[Third Embodiment]

5 <1>

Applied examples of the visual processing devices, visual processing methods, and visual processing programs described above in the first and second embodiments, and a system using the same, are described below as a third embodiment of the present invention.

10 The visual processing device is a device for processing images that is provided in or connected to a machine that handles images, such as a computer, a television, a digital camera, a portable telephone, a PDA, a printer, or a scanner, and is achieved by an integrated circuit such as an LSI.

15 More specifically, each functional block of the foregoing embodiments can each be separately achieved as single chips, or can be achieved by a single chip that incorporates some or all of those functions. It should be noted that here reference is made to LSIs, but depending on the degree of integration, these may also be referred to as ICs, system
20 LSIs, super LSIs, or ultra LSIs.

Further, the manner in which the ~~circuit-circuit~~ integration is achieved is not limited to LSIs, and it is also possible to use a dedicated circuit or a general purpose processor. After LSI manufacturing, it is also possible to employ a programmable FPGA (Field Programmable
25 Gate Array) or a reconfigurable processor in which the connections and settings of the circuit cells within the LSI can be reconfigured.

Further, if other technologies that improve upon or are derived from semiconductor technology enable integration technology to replace LSIs, then naturally it is also possible to integrate the functional blocks

using that technology. Biotechnology applications are one such foreseeable example.

The various blocks of the visual processing devices described above in the first and second embodiments are for example processed by
5 a central processing unit (CPU) provided in the visual processing device. Also, a program for performing those processes is stored on a memory device such as a hard disk or a ROM, and this program is run on the ROM, or read to and run on a RAM.

The two-dimensional LUT 4 in the visual processing device 1 of
10 Fig. 1 is stored on a memory device such as a hard disk or ROM, and is referenced when necessary. Further, the visual processing device 3 receives profile data that are provided to it from the profile data registration device 8, which is connected to the visual processing device 1 directly or indirectly over a network, and these are registered as the
15 two-dimensional LUT 4.

The visual processing device can also be a device that performs gradation processing of the images of each frame (each field) that is provided in or is connected to a device that handles moving images.

The visual processing method described in the first embodiment
20 is executed on the visual processing device 1.

The visual processing program is a program for executing visual processing of images, and is stored on a memory device such as a hard disk or ROM in a device provided in or connected to a machine that handles images, such as a computer, a television, a digital camera, a
25 portable telephone, a PDA, a printer, or a scanner. The program is for example provided via a storage medium such as a CD-ROM or via a network.

<2>

It is also possible for the visual processing devices described

above in the first and second embodiments to be expressed by the configurations shown in Fig. 40 and Fig. 41.

(1)

<<Configuration>>

5 Fig. 40 is a block diagram that shows the configuration of a visual processing device 910 that achieves the same functions as the visual processing device 525 shown using Fig. 7 for example.

 In the visual processing device 910, a sensor 911 and a user input portion 912 have the same functions as the input device 527 (see Fig. 7).
10 More specifically, the sensor 911 is a sensor that detects the ambient light in the environment in which the visual processing device 910 has been placed, or in the environment in which the output signal OS from the visual processing device 910 is displayed, and outputs the detected value as a parameter P1 that expresses the ambient light. The user
15 input portion 912 is a device through which the user can set the intensity of the ambient light in a stepwise manner, such as “strong, medium, weak,” or in a non-stepwise manner (i.e. in a continuous manner), and outputs the value that is set as a parameter P1 that expresses the ambient light.

20 An output portion 914 has the same function as the profile data registration portion 526 (see Fig. 7). More specifically, the output portion 914 is provided with data of a plurality of profiles corresponding to the values of the parameter P1, which expresses the ambient light. Here, the profile data are data in a table format that give a value of an
25 output signal OS with respect to the input signal IS and the signal obtained by spatially processing the input signal IS. Further, the output portion 914 outputs profile data corresponding to the value of the parameter P1, which expresses the ambient light, that has been obtained to a transformation portion 915 as a luminance adjustment parameter

P2.

The transformation portion 915 has the same function as the spatial processing portion 2 and the visual processing portion 3 (see Fig. 7). The transformation portion 915 receives the luminance of the pixel in question (target pixel) to be subjected to visual processing, the luminance of the surrounding pixels positioned around the target pixel, and the luminance adjustment parameter P2 as input, transforms the luminance of the target pixel, and outputs the result as the output signal OS.

More specifically, the transformation portion 915 spatially processes the target pixel and the surrounding pixels. The transformation portion 915 also reads the value of the output signal OS corresponding to the pixel being processed and the result of the spatial processing from the values of the luminance adjustment parameter P2, which are in a table format, and outputs this as the output signal OS.

<<Modified Examples>>

(1)

In the above configuration, the luminance adjustment parameter P2 is not limited to the above-described profile data. For example, it is also possible for the luminance adjustment parameter P2 to be coefficient matrix data used when computing the value of the output signal OS from the luminance of the pixel being processed and the luminance of the surrounding pixels. Here, coefficient matrix data are data storing the coefficient portion of the function used when computing the value of the output signal OS from the luminance of the pixel being processed and the luminance of the surrounding pixels.

(2)

It is not necessary for the output portion 914 to be provided with profile data or coefficient matrix data for all the values of the parameter

P1, which expresses the ambient light. In this case, it is also possible to suitably interpolate or extrapolate the profile data e.g. that have been provided in correspondence with the parameter P1, which expresses the ambient light, that has been obtained, so as to create appropriate profile data e.g.

(2)

<<Configuration>>

Fig. 41 is a block diagram that shows the configuration of a visual processing device 920 that has the same functions as the visual processing device 600 shown using Fig. 24.

With the visual processing device 920, the output portion 921 further obtains an outside parameter P3 in addition to the parameter P1, which expresses the ambient light, and outputs the luminance adjustment parameter P2 based on the parameter P1, which expresses the ambient light, and the outside parameter P3.

Here, the parameter P1 that expresses the ambient light is the same as that described in (1) above.

The outside parameter P3 is a parameter expressing e.g. the visual effect desired by the user who will view the output signal OS. More specifically, it is a value such as the contrast desired by the user who will view the image (target contrast). Here, the outside parameter P3 is set by the target contrast setting portion 604 (see Fig. 24). Alternatively, it is set using a default value stored on the output portion 921 in advance.

The output portion 921 calculates the value of the actual contrast through the configuration shown in Fig. 33 and Fig. 34 from the parameter P1, which expresses the ambient light, and outputs the result as the luminance adjustment parameter P2. The output portion 921 outputs the outside parameter P3 (target contrast) as the luminance

adjustment parameter P2. The output portion 921 also stores data of a plurality of profiles stored in the two-dimensional LUT described in [Second Embodiment] <Modified Example> (vii), and selects profile data based on the actual contrast that has been calculated from the outside
5 parameter P3 and the parameter P1, which expresses the ambient light, and outputs this data, which is in the form of a table, as the luminance adjustment parameter P2.

A transformation portion 922 has the same function as the target contrast transformation portion 601, the transformed signal processing
10 portion 602, and the actual contrast transformation portion 603 (for these, see Fig. 24). More specifically, the transformation portion 922 receives the input signal IS (luminance of the pixel being processed and luminance of the surrounding pixels) and the luminance adjustment parameter P2 as input, and outputs an output signal OS. For example,
15 the input signal IS is transformed into the target contrast signal JS (see Fig. 24) using the target contrast obtained as the luminance adjustment parameter P2. It then spatially processes the target contrast signal JS, thus deriving the unsharp signal US (see Fig. 24).

The transformation portion 922 is provided with the visual
20 processing portion 623 of the modified example described in [Second Embodiment] <Modified Example> (vii), and outputs the visually processed signal KS (see Fig. 24) from the profile data obtained as the luminance adjustment parameter P2, the target contrast signal JS, and the unsharp signal US. The visually processed signal KS is then
25 transformed into the output signal OS using the actual contrast that is obtained as the luminance adjustment parameter P2.

With the visual processing device 920, it is possible to select the profile data to be used for visual processing based on the outside parameter P3 and the parameter P1, which expresses the ambient light,

and also, it is possible to compensate for the effect of the ambient light to improve the local contrast, even in an environment where ambient light is present, bringing the contrast closer to the contrast desired by the user who will view the output signal OS.

5 <<Modified Examples>>

It should be noted that it is possible to perform the same modifications as those discussed in (1) with this configuration as well.

Where necessary, it is also possible to switch the configuration described in (1) and the configuration described in (2). This switching
10 can be performed using a switch signal from the outside. It is also possible to determine which of the configurations to use based on whether or not the outside parameter P3 is present.

Although the actual contrast was described as being calculated by the output portion 921, it is also possible to adopt a configuration in
15 which the value of the actual contrast is directly input to the output portion 921.

(3)

With the configuration shown in Fig. 41, it is further possible to adopt means for keeping the input from the output portion 921 to the
20 transformation portion 922 from changing abruptly.

A visual processing device 920' shown in Fig. 42 differs from the visual processing device 920 shown in Fig. 41 in that it is further provided with an adjustment portion 925 that eases the change over time in the parameter P1, which expresses the ambient light. The
25 adjustment portion 925 receives the parameter P1 expressing the ambient light as input and outputs a post-adjustment output P4.

By doing this, it becomes possible for the output portion 921 to obtain a parameter P1 that expresses the ambient light that does not change abruptly, and as a result, the change in the output of the output

portion 921 over time also becomes gentle.

The adjustment portion 925 is achieved by an IIR filter, for example. Here, with an IIR filter, the value [P4] of the output P4 of the adjustment portion 925 is calculated by $[P4] = k1*[P4]' + k2*[P1]$. In the equation, k1 and k2 are each parameters that take a positive value, [P1] is the value of the parameter P1, which expresses the ambient light, and [P4]' is the value of the delay output (for example, the previous output) of the output P4 of the adjustment portion 925. It should be noted that the processing in the adjustment portion 925 can also be performed using a component other than an IIR filter.

Further, it is also possible for the adjustment portion 925 to be means that directly smoothes the change in the luminance adjustment parameter P2 over time that is provided on the output side of the output portion 921, as in the visual processing device 920" shown in Fig. 43.

Here, the operation of the adjustment portion 925 is the same as that described above. More specifically, the value [P4] of the output P4 of the adjustment portion 925 is calculated by $[P4] = k3*[P4]' + k4*[P2]$. In the equation, k3 and k4 are each parameters that take a positive value, [P2] is the value of the luminance adjustment parameter P2, and [P4]' is the value of the delay output (for example, the previous output) of the output P4 of the adjustment portion 925. It should be noted that the processing in the adjustment portion 925 can also be performed using a component other than an IIR filter.

With the configuration shown in Figs. 42 and 43, for example, it is possible to control the change over time of the parameter P1 expressing the ambient light or the luminance adjustment parameter P2. Thus, it is possible to inhibit sudden parameter fluctuations, even if the sensor 911 for detecting the ambient light responds to a person who has moved in front of the sensor and for a brief moment the parameters

significantly change. As a result, flickering in the display screen can be inhibited.

[Fourth Embodiment]

5 An example of the application of the visual processing devices, the visual processing methods and the visual processing programs, as well as a system using the same according to a fourth example of the present invention are described with reference to Figs. 44 to 47.

10 Fig. 44 is a block diagram showing an overall structure of a content providing system ex100 that realizes a content delivering service. An area where a communication service is provided is divided into cells of a desired size, and base stations ex107-ex110 that are fixed radio stations are provided in the cells.

15 This content providing system ex100 includes a computer ex111, a personal digital assistant (PDA) ex112, a camera ex113, a cellular phone ex114, a cellular phone with camera ex115 and other equipment that are connected to the Internet ex101 for example via an internet service provider ex102, a telephone network ex104 and base stations ex107-ex110.

20 However, the content providing system ex100 can adopt any combination for connection without being limited to the combination shown in Fig. 44. In addition, each of the devices can be connected directly to the telephone network ex104 without the base stations ex107-ex110 that are fixed radio stations.

25 The camera ex113 is a device such as a digital video camera that can obtain a moving image. In addition, the cellular phone may be any type of PDC (Personal Digital Communications) method, CDMA (Code Division Multiple Access) method, W-CDMA (Wideband-Code Division Multiple Access) method, or GSM (Global System for Mobile

Communications) method, or a cellular phone of PHS (Personal Handyphone System).

In addition, the streaming server ex103 is connected to the camera ex113 via the base station ex109 and the telephone network
5 ex104, so that live delivery can be performed on the basis of coded data transmitted by a user of the camera ex113. The coding process of the obtained data may be performed by the camera ex113 or by a server for transmitting data. In addition, the moving image data obtained by the camera ex116 may be transmitted to the streaming server ex103 via the
10 computer ex111. The camera ex116 is a device that can take a still image like a digital camera and a moving image. In this case, coding of the moving image data may be performed by the camera ex116 or by the computer ex111. In addition, the coding process may be performed by an LSI ex117 in the computer ex111 or the camera ex116. Note that it is
15 possible to incorporate software for coding and decoding images into a storage medium (a CD-ROM, a flexible disk, a hard disk or the like) that is a recording medium readable by the computer ex111. Furthermore, the cellular phone with camera ex115 may transmit the moving image data. In this case, the moving image data is coded by the LSI in the
20 cellular phone ex115.

In this content providing system ex100, content (for example, a moving image of a music concert) that the user is recording with the camera ex113 or the camera ex116 are coded as shown in the above-described embodiments and transmitted to the streaming server
25 ex103, while the streaming server ex103 delivers a stream of the content data to a client who made a request. The client may be the computer ex111, the PDA ex112, the camera ex113, the cellular phone ex114 or the like that can decode the coded data. Thus, in the content providing system ex100, the client can receive and reproduce the coded data. The

system can realize personal broadcasting when the client receives, decodes and reproduces the stream in real time.

To display the content, the visual processing devices, the visual processing methods and the visual processing programs may be used.

- 5 For example, the computer ex111, the PDA ex112, the camera ex113, the cellular phone ex114 or the like may be provided with the visual processing devices and execute the ~~the~~ visual processing methods and the visual processing programs.

- The streaming server ex103 may be a device which provides the
10 visual processing device with the profile data through the Internet ex101. Moreover, a plurality of the streaming servers ex103 may be exist and each of the streaming servers ex103 may provide different profile datas. Furthermore, the streaming server ex103 may produce the profile data. If the visual processing device can obtain the profile data through the
15 Internet ex101, it is not necessary for the visual processing device to store a large number of profiles for the visual processing in advance, and this allows the storage capacity for the profiles to be reduced. Further, by obtaining the profiles from different servers which locate on the Internet ex101, it is possible for the visual processing device to execute
20 different image processings.

An example regarding a cellular phone will now be described.

- Fig. 45 shows the cellular phone ex115 that utilizes the visual processing devices of the present invention. The cellular phone ex115 includes an antenna ex201 for transmitting and receiving radio waves
25 with the base station ex110, a camera portion ex203 such as a CCD camera that can take a still image, a display portion ex202 such as a liquid crystal display for displaying images obtained by the camera portion ex203 or images received by the antenna ex201 after the image data are decoded, a main body portion including a group of operating

keys ex204, a sound output portion ex208 such as a speaker for producing sounds, a sound input portion ex205 such as a microphone for receiving sounds, a recording medium ex207 for storing coded data or decoded data such as data of taken moving images or still images, data
5 of received e-mails, moving images or still images, and a slot portion ex206 that enables the recording medium ex207 to be attached to the cellular phone ex115. The recording medium ex207 such as an SD card includes a plastic case housing a flash memory element that is one type of EEPROM (Electrically Erasable and Programmable Read Only
10 Memory) nonvolatile memory that is electronically rewritable and erasable.

Furthermore, the cellular phone ex115 will be described with reference to Fig. 46. The cellular phone ex115 includes a main controller portion ex311 for controlling each portion of the main body
15 portion having the display portion ex202 and the operating keys ex204, a power source circuit portion ex310, an operational input controller portion ex304, an image coding portion ex312, a camera interface portion ex303, an LCD (Liquid Crystal Display) controller portion ex302, an image decoding portion ex309, a multiplex separation portion ex308, a
20 recording and reproduction portion ex307, a modem circuit portion ex306 and a sound processing portion ex305, which are connected to each other via a synchronizing bus ex313.

When the user turns on a clear and power key, the power source circuit portion ex310 supplies power from a battery pack to each portion
25 so that the digital cellular phone with camera ex115 is activated.

The cellular phone ex115 converts a sound signal collected by the sound input portion ex205 during a sound communication mode into digital sound data by the sound processing portion ex305 under control of the main controller portion ex311 that includes a CPU, a ROM and a

RAM. The digital sound data are processed by the modem circuit portion ex306 as a spectrum spreading process and are processed by the transmission and reception circuit portion ex301 as a digital to analog conversion process and a frequency conversion process. After that, the data are transmitted via the antenna ex201. In addition, the cellular phone ex115 amplifies a signal that is received by the antenna ex201 during the sound communication mode and performs the frequency conversion process and an analog to digital conversion process on the data, which is processed by the modem circuit portion ex306 as a spectrum inverse spreading process and is converted into an analog sound signal by the sound processing portion ex305. After that, the analog sound signal is delivered by the sound output portion ex208.

Furthermore, when transmitting electronic mail during a data communication mode, text data of the electronic mail are entered by using the operating keys ex204 of the main body portion and are given to the main controller portion ex311 via the operational input controller portion ex304. The main controller portion ex311 performs the spectrum spreading process on the text data by the modem circuit portion ex306 and performs the digital to analog conversion process and the frequency conversion process by the transmission and reception circuit portion ex301. After that, the data are transmitted to the base station ex110 via the antenna ex201.

When transmitting image data during the data communication mode, the image data obtained by the camera portion ex203 are supplied to the image coding portion ex312 via the camera interface portion ex303. In addition, if the image data are not transmitted, it is possible to display the image data obtained by the camera portion ex203 directly by the display portion ex202 via the camera interface portion ex303 and an LCD controller portion ex302.

The image coding portion ex312 converts the image data supplied from the camera portion ex203 into the coded image data by compressing and coding the data, and the coded image data are supplied to the multiplex separation portion ex308. In addition, the cellular phone
5 ex115 collects sounds by the sound input portion ex205 while the camera portion ex203 is taking the image, and the digital sound data is supplied from the sound processing portion ex305 to the multiplex separation portion ex308.

The multiplex separation portion ex308 performs multiplexing of
10 the coded image data supplied from the image coding portion ex312 and the sound data supplied from the sound processing portion ex305 by a predetermined method. Multiplexed data obtained as a result are processed by the modem circuit portion ex306 as a spectrum spreading process and are processed by the transmission and reception circuit
15 portion ex301 as a digital to analog conversion process and a frequency conversion process. After that, the data are transmitted via the antenna ex201.

When receiving moving image file data that are linked to a web page during the data communication mode, a signal received from the
20 base station ex110 via the antenna ex201 is processed by the modem circuit portion ex306 as a spectrum inverse spreading process. Multiplexed data obtained as a result are supplied to the multiplex separation portion ex308.

In addition, in order to decode multiplexed data received via the
25 antenna ex201, the multiplex separation portion ex308 separates a coded bit stream of image data in the multiplexed data from a coded bit stream of sound data. Then, the multiplex separation portion ex308 supplies the coded image data to the image decoding portion ex309 via the synchronizing bus ex313 and supplies the sound data to the sound

processing portion ex305.

Next, the image decoding portion ex309 generates reproduction moving image data by decoding the coded bit stream of the image data and supplies the data to the display portion ex202 via the LCD controller
5 portion ex302. Thus, the moving image data included in a moving image file that is linked to a home page can be displayed. In this case, the sound processing portion ex305 converts the sound data into an analog sound signal, which is supplied to the sound output portion ex208. Thus, sound data included in the moving image file that is
10 linked to a home page can be reproduced.

Note that the image decoding portion ex309 may be provided with the visual processing device shown in the above-described embodiments.

Note that the present invention is not limited to the example of the system described above. Digital broadcasting by satellite or
15 terrestrial signals has been a recent topic of discussion. As shown in Fig. 47, the visual processing devices, the visual processing methods and the visual processing programs of the present invention can be incorporated into the digital broadcasting system, too.

More specifically, in a broadcast station ex409, a coded bit stream
20 of image information is sent to a communication or a broadcasting satellite ex410 via a radio wave. The broadcasting satellite ex410 that received the coded bit stream of image information sends radio waves for broadcasting. These radio waves are received by an antenna ex406 of a house equipped with a satellite broadcasting reception facility, and a
25 device such as a television set (a receiver) ex401 or a set top box (STB) ex407 decodes the coded bit stream and reproduces the same. In addition, the television set (the receiver) ex401 or the set top box (STB) ex407 may be provided with the visual processing devices shown in the above-described embodiments, use the visual processing methods shown

in the above-described embodiments or execute the visual processing programs shown in the above-described embodiments. In addition, a reproduction device ex403 for reading and decoding a coded bit stream that is recorded on a storage medium ex402 such as a CD or a DVD that
5 is a recording medium may be equipped with the visual processing devices, the visual processing methods or the visual processing programs shown in the above-described embodiments. In this case, the reproduced image signal and text track are displayed on a monitor ex404. In addition, it is possible to mount the visual processing devices, the
10 visual processing methods or the visual processing programs shown in the above-described embodiments, in a set top box ex407 that is connected to a cable ex405 for a cable television or the antenna ex406 for a satellite or surface wave broadcasting, so that the image can be reproduced on a monitor ex408 of the television set. In this case, it is
15 possible to incorporate the visual processing devices shown in the above-described embodiments not into the set top box but into the television set. In addition, it is possible that a car ex412 equipped with an antenna ex411 receives a signal from the broadcasting satellite ex410 or the base station ex107 and reproduces the moving image on a display
20 of a navigation system ex413 in the car ex412.

Furthermore, it is possible to encode the image signal and record the encoded image signal in a recording medium. As a specific example, there is a recorder ex420 such as a DVD recorder for recording image signals on a DVD disk ex421 or a disk recorder for recording image
25 signals on a hard disk. Furthermore, it is possible to record on an SD card ex422. In addition, in case that the recorder ex420 includes the decoding apparatus of the present invention, it is possible to reproduce image signals recorded on a DVD disk ex421 or a SD card ex422 via the image signal processing device, so as to display on the monitor ex408.

Note that in the structure of the navigation system ex413 shown in Fig. 46, the camera portion ex203, the camera interface portion ex303 and the image coding portion ex312 can be omitted. This can be also applied to the computer ex111 and the television set (the receiver) ex401.

5 In addition, the terminal device such as the cellular phone ex114 may include three types of assemblies. A first type is a transmission and reception terminal having both the coder and the decoder, a second type is a transmission terminal having only a coder and a third type is a reception terminal having only a decoder.

10 Thus, the visual processing devices, the visual processing methods or the visual processing programs shown in the above-described embodiments can be used for any device and system described above, so that effects described above can be obtained.

15 [Attachment]

The present invention can also be expressed as follows.

<Content of the Attachment>

(Attachment 1)

A visual processing device comprising:

20 image signal processing means that performs spatial processing of an image signal that has been received as input, and outputs a processed signal; and

 signal computation means that outputs an output signal based on a computation for emphasizing the respective differences in the image
25 signal and the processed signal after each has been transformed by a predetermined transformation.

(Attachment 2)

The visual processing device according to attachment 1,

wherein the signal computation means computes a value C of the output signal with respect to a value A of the image signal, a value B of the processed signal, a transformation function F1, an inverse transformation function F2 of the transformation function F1, and the enhancement function F3, according to the equation $F2(F1(A) + F3(F1(A)-F1(B)))$.

(Attachment 3)

The visual processing device according to attachment 2,
10 wherein the transformation function F1 is a logarithmic function.

(Attachment 4)

The visual processing device according to attachment 2,
wherein the inverse transformation function F2 is a gamma
15 correction function.

(Attachment 5)

The visual processing device according to any one of attachments 2 to 4,
20 wherein the signal computation means has signal space transformation means that transforms the signal space of the image signal and the processed signal, enhancement processing means that performs enhancement processing of a difference signal of the difference between the image signal after transformation and the processed signal
25 after transformation, and inverse transformation means that performs inverse transformation of the signal space with respect to a sum signal obtained by summing the image signal after transformation and the difference signal after enhancement processing and outputs the result as the output signal.

(Attachment 6)

A visual processing device comprising:

5 image signal processing means that performs spatial processing
of an image signal that has been received as input, and outputs a
processed signal; and

signal computation means that outputs an output signal based on
a computation for emphasizing the ratio between the image signal and
the processed signal.

10

(Attachment 7)

The visual processing device according to attachment 6,
wherein the signal computation means outputs the output signal
based on said calculation in which dynamic range compression of the
15 image signal is further performed.

(Attachment 8)

The visual processing device according to attachment 6 or 7,
wherein the signal computation means computes a value C of the
20 output signal with respect to a value A of the image signal, a value B of
the processed signal, a dynamic range compression function F4, and the
enhancement function F5, according to the equation $F4(A) * F5(A/B)$.

(Attachment 9)

25 The visual processing device according to attachment 8,
wherein the dynamic range compression function F4 is a direct
proportion function of a proportion coefficient 1.

(Attachment 10)

The visual processing device according to attachment 8,
wherein the dynamic range compression function F4 is a
~~monotonously~~ monotonically increasing function.

5 (Attachment 11)

The visual processing device according to attachment 10,
wherein the dynamic range compression function F4 is a concave
function.

10 (Attachment 12)

The visual processing device according to attachment 8,
wherein the dynamic range compression function F4 is a power
function.

15 (Attachment 13)

The visual processing device according to attachment 12,
wherein the exponent of the power function in the dynamic range
compression function F4 is determined based on a target contrast value,
which is a target value of the contrast when displaying the image, and
20 an actual contrast value, which is a contrast value in the display
environment when displaying the image.

(Attachment 14)

The visual processing device according to any one of attachments
25 8 to 13,
wherein the enhancement function F5 is a power function.

(Attachment 15)

The visual processing device according to attachment 14,

wherein the exponent of the power function in the enhancement function F5 is determined based on a target contrast value, which is a target value of the contrast when displaying the image, and an actual contrast value, which is a contrast value in the display environment
5 when displaying the image.

(Attachment 16)

The visual processing device according to attachment 14 or 15,
wherein the exponent of the power function in the enhancement
10 function F5 is a value that decreases monotonically with respect to the value A of the image signal in a case where the value A of the image signal is larger than the value B of the processed signal.

(Attachment 17)

15 The visual processing device according to attachment 14 or 15,
wherein the exponent of the power function in the enhancement function F5 is a value that increases monotonically with respect to the value A of the image signal in a case where the value A of the image signal is smaller than the value B of the processed signal.

20

(Attachment 18)

The visual processing device according to attachment 14 or 15,
wherein the exponent of the power function in the enhancement function F5 is a value that increases monotonically with respect to the
25 value A of the image signal in a case where the value A of the image signal is larger than the value B of the processed signal.

(Attachment 19)

The visual processing device according to attachment 14 or 15,

wherein the exponent of the power function in the enhancement function F5 is a value that increases monotonically with respect to the absolute value of the difference between the value A of the image signal and the value B of the processed signal.

5

(Attachment 20)

The visual processing device according to any one of attachment 14 to 19,

wherein at least one of a maximum value or a minimum value of the enhancement function F5 is kept within a predetermined range.

10

(Attachment 21)

The visual processing device according to attachment 8,

wherein the signal computation means has enhancement processing means that performs enhancement processing of a divided signal that is obtained by dividing the image signal by the processed signal, and output processing means that outputs the output signal based on the image signal and the divided signal that has been subjected to enhancement processing.

15

20

(Attachment 22)

The visual processing device according to attachment 21,

wherein the output processing means obtains the product of the image signal and the divided signal that has been subjected to enhancement processing.

25

(Attachment 23)

The visual processing device according to attachment 21,

wherein the output processing means includes DR compression

means that performs dynamic range (DR) compression with respect to the image signal, and obtains the product of the image signal after DR compression and the divided signal that has been subjected to enhancement processing.

5

(Attachment 24)

The visual processing device according to any one of attachments 8 to 23, further comprising:

first transformation means that transforms input image data of a
10 first predetermined range to a second predetermined range, and outputs this as the image signal; and

second transformation means that transforms the output signal of a third predetermined range to a fourth predetermined range, and outputs this as output image data;

15 wherein the second predetermined range is determined based on the target contrast value, which is the target value of the contrast when the image is displayed; and

wherein the third predetermined range is determined based on the actual contrast value, which is the contrast value in the display
20 environment when the image is displayed.

(Attachment 25)

The visual processing device according to attachment 24,

wherein the dynamic range compression function F4 is a function
25 that transforms image signal of the second predetermined range into the output signal of the third predetermined range.

(Attachment 26)

The visual processing device according to attachment 24 or 25,

wherein the first transformation means transforms the minimum value and the maximum value of the first predetermined range into the minimum value and the maximum value, respectively, of the second predetermined range; and

5 wherein the second transformation means transforms the minimum value and the maximum value of the third predetermined range into the minimum value and the maximum value, respectively, of the fourth predetermined range.

10 (Attachment 27)

The visual processing device according to attachment 26,
wherein the transformations by the first transformation means
and the second transformation means are linear transformations.

15 (Attachment 28)

The visual processing device according to any one of attachments
24 to 27, further comprising:
setting means that sets the third predetermined range.

20 (Attachment 29)

The visual processing device according to attachment 28,
wherein the setting means includes storage means that stores a
dynamic range of the display device for displaying an image, and
measuring means that measures the luminance of the ambient light in
25 the display environment when displaying an image.

(Attachment 30)

The visual processing device according to attachment 28,
wherein the setting means includes measuring means that

measures the luminance in the display environment of the display device for displaying an image when displaying black level and when displaying white level.

5 (Attachment 31)

A visual processing device comprising:

input signal processing means that performs spatial processing of an image signal that has been received as input, and outputs a processed signal; and

10 signal computation means that outputs an output signal based on a computation for enhancing a difference between the image signal and the processed signal in accordance with a value of the image signal.

(Attachment 32)

15 The visual processing device according to attachment 31, wherein the signal computation means outputs the output signal based on a computation that adds a value that is obtained by compressing the dynamic range of the image signal to the enhanced value from the computation for enhancing.

20

(Attachment 33)

The visual processing device according to attachment 31 or 32,

wherein the signal computation means computes a value C of the output signal with respect to a value A of the input signal, a value B of the processed signal, an enhancement amount adjustment function F6, an enhancement function F7, and a dynamic range compression function F8, according to the equation $F8(A) + F6(A) * F7(A-B)$.

25

(Attachment 34)

The visual processing device according to attachment 33,
wherein the dynamic range compression function F8 is a direct
proportion function of a proportion coefficient 1.

5 (Attachment 35)

The visual processing device according to attachment 33,
wherein the dynamic range compression function F8 is a
~~monotonously~~monotonically increasing function.

10 (Attachment 36)

The visual processing device according to attachment 35,
wherein the dynamic range compression function F8 is a concave
power function.

15 (Attachment 37)

The visual processing device according to attachment 33,
wherein the dynamic range compression function F8 is a power
function.

20 (Attachment 38)

The visual processing device according to attachment 33,
wherein the signal computation means has enhancement
processing means that performs enhancement processing of a difference
signal of the difference between the image signal and the processed
25 signal in accordance with the pixel value of the image signal, and output
processing means that outputs the output signal based on the image
signal and the enhanced difference signal.

(Attachment 39)

The visual processing device according to attachment 38,
wherein the output processing means performs a summing
process of taking the sum of the image signal and the enhanced
difference signal.

5

(Attachment 40)

The visual processing device according to attachment 38,
wherein the output processing means includes DR compression
means that performs dynamic range (DR) compression with respect to
10 the image signal, and performs a summing process of taking the sum of
the DR compressed image signal and the enhanced difference signal.

(Attachment 41)

A visual processing device comprising:
15 input signal processing means that performs spatial processing of
an image signal that has been received as input, and outputs a processed
signal; and

signal computation means that outputs an output signal based on
a computation that adds a value obtained by correcting the gradation of
20 the image signal to the value obtained by enhancing the difference
between the image signal and the processed signal.

(Attachment 42)

The visual processing device according to attachment 41,
25 wherein the signal computation means computes a value C of the
output signal with respect to a value A of the input signal, a value B of
the processed signal, an enhancement function F11, and a gradation
correction function F12, according to the equation $F12(A) + F11(A-B)$.

(Attachment 43)

The visual processing device according to attachment 42,

wherein the signal computation means has enhancement
processing means that performs enhancement processing of a difference
5 signal of the difference between the image signal and the processed
signal, and summing means that takes the sum of the
gradation-corrected image signal and the enhanced difference signal and
outputs the result as an output signal.

10 (Attachment 44)

A visual processing method comprising:

a first transformation step of transforming an input image data
of a first predetermined range to a second predetermined range, and
taking this as an image signal;

15 a signal computation step of outputting an output signal of a
third predetermined range based on a computation that includes at least
one of a computation for compressing the dynamic range of the image
signal, and a computation for enhancing a ratio between the image
signal and a processed signal that is obtained by spatially processing the
20 image signal; and

a second transformation step of transforming the output signal of
the third predetermined range to a fourth predetermined range, and
taking this as output image data;

wherein the second predetermined range is determined based on
25 a target contrast value, which is a target value of the contrast when the
image is displayed; and

wherein the third predetermined range is determined based on an
actual contrast value, which is a contrast value in the display
environment when the image is displayed.

(Attachment 45)

A visual processing device comprising:

first transformation means that transforms input image data of a
5 first predetermined range to a second predetermined range, and takes
this as an image signal;

signal computation means that outputs an output signal of a
third predetermined range based on a computation that includes at least
one of a computation for compressing the dynamic range of the image
10 signal, and a computation for enhancing a ratio between the image
signal and a processed signal that is obtained by spatially processing the
image signal; and

second transformation means that transforms the output signal
of the third predetermined range to a fourth predetermined range, and
15 takes this as output image data;

wherein the second predetermined range is determined based on
a target contrast value, which is a target value of the contrast when the
image is displayed; and

wherein the third predetermined range is determined based on an
20 actual contrast value, which is a contrast value in the display
environment when the image is displayed.

(Attachment 46)

A visual processing program for causing a computer to perform
25 visual processing, the visual processing program causing the computer to
perform a visual processing method comprising:

a first transformation step of transforming an input image data
of a first predetermined range to a second predetermined range, and
taking this as an image signal;

a signal computation step of outputting an output signal of a third predetermined range based on a computation that includes at least one of a computation for compressing the dynamic range of the image signal, and a computation for enhancing a ratio between the image
5 signal and a processed signal that is obtained by spatially processing the image signal; and

a second transformation step of transforming the output signal of the third predetermined range to a fourth predetermined range, and taking this as output image data;

10 wherein the second predetermined range is determined based on a target contrast value, which is a target value of the contrast when the image is displayed; and

wherein the third predetermined range is determined based on an actual contrast value, which is a contrast value in the display
15 environment when the image is displayed.

<Description of the Attachment>

The visual processing device according to attachment 1 is provided with image signal processing means and signal computation
20 means. The image signal processing means performs spatial processing of an image signal that has been received as input, and outputs a processed signal. The signal computation means outputs an output signal based on a computation for emphasizing the respective differences in the image signal and the processed signal after each has been
25 transformed by a predetermined transformation.

Here, spatial processing for example refers to processing in which a low pass spatial filter is adopted for the image signal that is received as input, or processing for deriving a mean value, a maximum value, or a minimum value of the pixel being processed and the surrounding pixels

of the image signal that is received as input (the same applies in the following). Also, the computation for enhancing is for example a computation for adjusting the gain, a computation for inhibiting extreme contrasts, or a computation for suppressing small amplitude noise components (the same applies in the following).

With the visual processing device of this invention, it is possible to enhance the respective differences in the image signal and the processed signal after these have been transformed to a separate space. Thus, it is possible to achieve enhancement that is suited for the viewing properties, for example.

The visual processing device according to attachment 2 is the visual processing device according to attachment 1 in which the signal computation means computes a value C of the output signal with respect to a value A of the image signal, a value B of the processed signal, a transformation function F1, an inverse transformation function F2 of the transformation function F1, and the enhancement function F3, according to the equation $F2(F1(A) + F3(F1(A) - F1(B)))$.

The enhancement function F3 is for example a function for adjusting the gain, a function for inhibiting extreme contrasts, or a function for suppressing small amplitude noise components.

Here, the value C of the output signal indicates the following. That is, the value A of the image signal and the value B of the processed signal are transformed into values in different spaces by the transformation function F1. The difference between the value of the image signal and the value of the processed signal after transformation represents a sharp signal, for example, in a separate space. The difference between the image signal and the processed signal after transformation, in which they are enhanced by the enhancement function F3, is added to the transformed image signal. Thus, the value

C of the output signal indicates a value that is obtained by enhancing the sharp signal component in a separate space.

With the visual processing device of this invention, it is for example possible to use the value A of the image signal and the value B
5 of the processed signal, which have been transformed to separate spaces, to perform processing such as edge enhancement or contrast enhancement in a separate space.

The visual processing device according to attachment 3 is the visual processing device according to attachment 2 in which the
10 transformation function F1 is a logarithmic function.

Here, human visual performance in general is logarithmic. Thus, by processing the image signal and the processed signal by transforming to logarithmic space, it is possible to perform visual processing that is suited for our visual characteristics.

15 With the visual processing device of this invention, it is possible to perform contrast enhancement having a high visual effect or dynamic range compression that maintains local contrast.

The visual processing device according to attachment 4 is the visual processing device according to attachment 2 in which the inverse
20 transformation function F2 is a gamma correction function.

Image signals in general are subjected to gamma correction through a gamma correction function based on to the gamma characteristics of the device that inputs and outputs the image signal.

With the visual processing device of this invention, with the
25 transformation function F1 it is possible to exclude gamma correction of the image signal and perform processing using linear characteristics. Thus, it is possible to correct optical blurring.

The visual processing device according to attachment 5 is the visual processing device according to any one of attachments 2 to 4, in

which the signal computation means has signal space transformation means, enhancement processing means, and inverse transformation means. The signal space transformation means transforms the signal space of the image signal and the processed signal. The enhancement
5 processing means performs enhancement processing of a differential signal between the image signal after transformation and the processed signal after transformation. The inverse transformation means performs inverse transformation of the signal space with respect to a sum signal obtained by summing the image signal after transformation
10 and the differential signal after enhancement processing and outputs the result as the output signal.

With the visual processing device of this invention, the signal space transformation means transforms the signal space of the image signal and the processed signal using the transformation function F1.
15 The enhancement processing means performs enhancement processing of a differential signal between the image signal after transformation and the processed signal after transformation. The inverse transformation means performs inverse transformation of the signal space with respect to a sum signal obtained by summing the image signal after
20 transformation and the difference signal after enhancement processing, using the inverse transformation function F2.

The visual processing device according to attachment 6 comprises input signal processing means and signal computation means. The input signal processing means performs spatial processing of an image
25 signal that has been received as input, and outputs a processed signal. The signal computation means outputs an output signal based on a computation for emphasizing the ratio between the image signal and the processed signal.

With the visual processing device of this invention, the ratio of

the image signal to the processed signal expresses the sharp component of the image signal. Thus, it is for example possible to perform visual processing for enhancing the sharp component.

5 The visual processing device according to attachment 7 is the visual processing device according to attachment 6 in which the signal computation means outputs the output signal based on the calculation in which dynamic range compression of the image signal is further performed.

10 With the visual processing device of this invention, it is possible to enhance the sharp component of the image signal, which expresses the ratio of the image signal to the processed signal, while performing compression of the dynamic range.

15 The visual processing device according to attachment 8 is the visual processing device according to attachment 6 or 7, in which the signal computation means computes a value C of the output signal with respect to a value A of the image signal, a value B of the processed signal, a dynamic range compression function F4, and the enhancement function F5, according to the equation $F4(A) * F5(A/B)$.

20 Here, the value C of the output signal shows the following. That is, the amount (A/B) obtained by dividing the value A of the image signal by the value B of the processed signal expresses the sharp signal, for example. Also, $F5(A/B)$ expresses the enhancement amount of the sharp signal, for example. These show processing equivalent to transforming the value A of the image signal and the value B of the processed signal
25 into logarithmic space and then enhancing the respective differences in each, performing enhancement processing that is suited for the visual characteristics.

With the visual processing device of this invention, it is possible to perform dynamic range compression where necessary while enhancing

local contrast.

The visual processing device according to attachment 9 is the visual processing device according to attachment 8 in which the dynamic range compression function F4 is a direct proportion function of a proportion coefficient 1.

With the visual processing device of this invention, it is possible to enhance the contrast of the image signal uniformly over a range spanning dark areas to bright areas. This contrast enhancement is enhancement processing that is suited for the visual characteristics.

The visual processing device according to attachment 10 is the visual processing device according to attachment 8 in which the dynamic range compression function F4 is a ~~monotonously-monotonically~~ increasing function.

With the visual processing device of this invention, it is possible to use the dynamic range compression function F4, which is a ~~monotonously-monotonically~~ increasing function, to perform dynamic range compression while enhancing local contrast.

The visual processing device according to attachment 11 is the visual processing device according to attachment 10 in which the dynamic range compression function F4 is a concave function.

With the visual processing device of this invention, it is possible to use the dynamic range compression function F4, which is a concave function, to perform dynamic range compression while enhancing local contrast.

The visual processing device according to attachment 12 is the visual processing device according to attachment 8 in which the dynamic range compression function F4 is a power function.

With the visual processing device of this invention, it is possible to use the dynamic range compression function F4, which is a power

function, to transform the dynamic range while enhancing local contrast.

The visual processing device according to attachment 13 is the visual processing device according to attachment 12 in which the exponent of the power function in the dynamic range compression function F4 is determined based on a target contrast value, which is a target value of the contrast when displaying the image, and an actual contrast value, which is a contrast value in the display environment when displaying the image.

Here, the target contrast value is the target value of the contrast when the image is displayed, and for example is a value that is determined by the dynamic range of the display device that will display the image. The actual contrast value is the contrast value in the display environment in which the image is to be displayed, and for example is a value that is determined by the contrast of the image displayed by the display device in a case where there is ambient light.

With the visual processing device of this invention, through the dynamic range compression function F4 it is possible to compress the dynamic range of an image signal having a dynamic range that is equal to the target contrast value to a dynamic range that is equal to the actual contrast value.

The visual processing device according to attachment 14 is the visual processing device according to any one of the attachments 8 to 13, in which the enhancement function F5 is a power function.

With the visual processing device of this invention, it is possible to use the enhancement function F5, which is a power function, to enhance local contrast, allowing the dynamic range to be transformed visually.

The visual processing device according to attachment 15 is the visual processing device according to attachment 14 in which the

exponent of the power function in the enhancement function F5 is determined based on a target contrast value, which is a target value of the contrast when displaying the image, and an actual contrast value, which is a contrast value in the display environment when displaying
5 the image.

With the visual processing device of this invention, it is possible to use the enhancement function F5, which is a power function, to enhance local contrast, allowing the dynamic range to be transformed visually.

10 The visual processing device according to attachment 16 is the visual processing device according to attachment 14 or 15 in which the exponent of the power function in the enhancement function F5 is a value that decreases monotonically with respect to the value A of the image signal in a case where the value A of the image signal is larger
15 than the value B of the processed signal.

With the visual processing device of this invention, of those pixels being processed having a higher luminance than the surrounding pixels in the image signal, it is possible to lower the enhancement of local contrast in high-luminance areas. Thus, it is possible to inhibit
20 “blooming” in the visually processed image.

The visual processing device according to attachment 17 is the visual processing device according to attachment 14 or 15 in which the exponent of the power function in the enhancement function F5 is a value that increase monotonically with respect to the value A of the
25 image signal in a case where the value A of the image signal is smaller than the value B of the processed signal.

With the visual processing device of this invention, of those pixels being processed having a lower luminance than the surrounding pixels in the image signal, it is possible to lower the enhancement of local contrast

in low-luminance areas. Thus, it is possible to inhibit “black squashing” in the visually processed image.

The visual processing device according to attachment 18 is the visual processing device according to attachment 14 or 15 in which the
5 exponent of the power function in the enhancement function F_5 is a value that increases monotonically with respect to the value A of the image signal in a case where the value A of the image signal is larger than the value B of the processed signal.

With the visual processing device of this invention, of those pixels
10 being processed having a higher luminance than the surrounding pixels in the image signal, it is possible to lower the enhancement of local contrast in low-luminance areas. Thus, the SN ratio is kept from becoming worse in the visually processed image.

The visual processing device according to attachment 19 is the
15 visual processing device according to attachment 14 or 15 in which the exponent of the power function in the enhancement function F_5 is a value that increases monotonically with respect to the absolute value of the difference between the value A of the image signal and the value B of the processed signal.

Here, it is also possible to define the value that monotonically
20 increases with respect to the absolute value of the difference between the value A of the image signal and the value B of the processed signal as a value that is greater in magnitude the closer the ratio of the value A of the image signal to the value B of the processed signal is to one.

25 With the visual processing device of this invention, it is possible to in particular enhance the local contrast of target pixels having little difference in brightness compared to the surrounding pixels in the image signal, and to keep from over enhancing the local contrast in pixels being processed having significant difference in brightness compared to the

surrounding pixels in the image signal.

The visual processing device according to attachment 20 is the visual processing device according to any one of attachments 14 to 19 in which at least one of a maximum value or a minimum value of the enhancement function F5 is kept within a predetermined range.

With the visual processing device of this invention, it is possible to keep the enhancement amount of the local contrast within an appropriate range.

The visual processing device according to attachment 21 is the visual processing device according to attachment 8 in which the signal computation means has enhancement processing means and output processing means. The enhancement processing means performs enhancement processing of a divided signal that is obtained by dividing the image signal by the processed signal. The output processing means outputs the output signal based on the image signal and the divided signal that has been subjected to enhancement processing.

With the visual processing device of this invention, enhancement processing means uses the enhancement function F5 to perform enhancement processing of a divided signal that is obtained by dividing the image signal by the processed signal. The output processing means outputs the output signal based on the image signal and the divided signal.

The visual processing device according to attachment 22 is the visual processing device according to attachment 21 in which the output processing means obtains the product of the image signal and the divided signal that has been subjected to enhancement processing.

With the visual processing device of this invention, the dynamic range compression function F4 is for example a direct proportion function of a proportion coefficient 1.

The visual processing device according to attachment 23 is the visual processing device according to attachment 21 in which the output processing means includes DR compression means that performs dynamic range (DR) compression with respect to the image signal, and
5 obtains the product of the image signal after DR compression and the enhanced divided signal.

With the visual processing device of this invention, the DR compression means performs dynamic range compression of the image signal using the dynamic range compression function F4.

10 The visual processing device according to attachment 24 is the visual processing device according to any one of attachments 8 to 23, further comprising first transformation means and second transformation means. The first transformation means transforms input image data of a first predetermined range to a second
15 predetermined range, and outputs this as the image signal. The second transformation means transforms the output signal of a third predetermined range to a fourth predetermined range, and outputs this as output image data. The second predetermined range is determined based on the target contrast value, which is the target value of the
20 contrast when the image is displayed. The third predetermined range is determined based on the actual contrast value, which is the contrast value in the display environment when the image is displayed.

With the visual processing device of this invention, it is possible to compress the dynamic range of the image overall down to the actual
25 contrast value that has dropped due to the presence of ambient light, while locally maintaining the target contrast value. Thus, the image after visual processing has an improved visual effect.

The visual processing device according to attachment 25 is the visual processing device according to attachment 24 in which the

dynamic range compression function F4 is a function that transforms the image signal of the second predetermined range into the output signal of the third predetermined range.

5 With the visual processing device of this invention, the dynamic range of the image overall is compressed down to the third predetermined range due to the dynamic range compression function F4.

 The visual processing device according to attachment 26 is the visual processing device according to attachment 24 or 25 in which the first transformation means transforms the minimum value and the maximum value of the first predetermined range into the minimum value and the maximum value, respectively, of the second predetermined range. The second transformation means transforms the minimum value and the maximum value of the third predetermined range into the minimum value and the maximum value, respectively, of the fourth predetermined range.

10

15

 The visual processing device according to attachment 27 is the visual processing device according to attachment 26 in which the transformations by the first transformation means and the second transformation means are linear transformations.

20 The visual processing device according to attachment 28 is the visual processing device according to any one of attachments 24 to 27, further comprising setting means that sets the third predetermined range.

 With the visual processing device of this invention, it is possible to set the third predetermined range in accordance with the display environment of the display device that is to display the image. Thus, it is possible to more suitably correct the ambient light.

25

 The visual processing device according to attachment 29 is the visual processing device according to attachment 28 in which the setting

means includes storage means that stores a dynamic range of the display device for displaying an image, and measuring means that measures the luminance of the ambient light in the display environment when displaying an image.

5 With the visual processing device of this invention, it is possible to measure the luminance of the ambient light and then determine the actual contrast value from the luminance that has been measured and the dynamic range of the display device.

 The visual processing device according to attachment 30 is the
10 visual processing device according to attachment 28 in which the setting means includes measuring means that measures the luminance in the display environment of the display device for displaying an image when displaying black level and when displaying white level.

 With the visual processing device of this invention, it is possible
15 to measure the luminance when displaying black level and when displaying white level in the display environment and from these to determine the actual contrast value.

 The visual processing device according to attachment 31 comprises input signal processing means and signal computation means.
20 The input signal processing means performs spatial processing of an image signal that has been received as input, and outputs a processed signal. The signal computation means outputs an output signal based on a computation for enhancing a difference between the image signal and the processed signal in accordance with a value of the image signal.

25 With the visual processing device of this invention, it is for example possible to enhance the sharp component of the image signal, which is the difference between the image signal and the processed signal, in accordance with the value of the image signal. Thus, it is possible to perform appropriate enhancement over a range spanning

dark areas to bright areas of the image signal.

The visual processing device according to attachment 32 is the visual processing device according to attachment 31 in which the signal computation means outputs the output signal based on a computation
5 that adds a value that is obtained by compressing the dynamic range of the image signal to the enhanced value from the computation for enhancing.

With the visual processing device of this invention, it is for example possible to enhance the sharp component, for example, of the
10 image signal in accordance with the value of the image signal and at the same time to compress the dynamic range.

The visual processing device according to attachment 33 is the visual processing device according to attachment 31 or 32 in which the signal computation means computes a value C of the output signal with
15 respect to a value A of the image signal, a value B of the processed signal, an enhancement amount adjustment function F6, an enhancement function F7, and a dynamic range compression function F8, according to the equation $F8(A) + F6(A) * F7(A-B)$.

Here, the value C of the output signal shows the following. That
20 is, the difference (A-B) between the value A of the image signal and the value B of the processed signal expresses the sharp signal, for example. Also, $F7(A-B)$ for example expresses the enhancement amount of the sharp signal. The enhancement amount is adjusted by the enhancement amount adjustment function F6 in accordance with the
25 value A of the image signal, and where necessary is added to the value of the image signal after its dynamic range has been compressed.

With the visual processing device of this invention, in areas where the value A of the image signal is large it is for example possible to maintain the contrast over a range spanning dark areas to bright

areas by reducing the enhancement amount, for example. It is possible to maintain local contrast over a range spanning dark areas to bright areas even when dynamic range compression has been performed.

5 The visual processing device according to attachment 34 is the visual processing device according to attachment 33 in which the dynamic range compression function F8 is a direct proportion function of a proportion coefficient 1.

10 With the visual processing device of this invention, it is possible to enhance the contrast uniformly over dark to bright areas of the image signal.

The visual processing device according to attachment 35 is the visual processing device according to attachment 33 in which the dynamic range compression function F8 is a ~~monotonously~~ monotonically increasing function.

15 With the visual processing device of this invention, it is possible to use the dynamic range compression function F8, which is a ~~monotonously~~ monotonically increasing function, to perform dynamic range compression while maintaining local contrast.

20 The visual processing device according to attachment 36 is the visual processing device according to attachment 35 in which the dynamic range compression function F8 is a concave function.

25 With the visual processing device of this invention, it is possible to use the dynamic range compression function F8, which is a concave function, to perform dynamic range compression while maintaining local contrast.

The visual processing device according to attachment 37 is the visual processing device according to attachment 33 in which the dynamic range compression function F8 is a power function.

With the visual processing device of this invention, it is possible

to use the dynamic range compression function F8, which is a power function, to transform the dynamic range while maintaining local contrast.

The visual processing device according to attachment 38 is the
5 visual processing device according to attachment 33 in which the signal computation means has enhancement processing means and output processing means. The enhancement processing means performs enhancement processing of a difference signal of the difference between the image signal and the processed signal in accordance with the pixel
10 value of the image signal. The output processing means outputs the output signal based on the image signal and the enhanced difference signal.

With the visual processing device of this invention, the enhancement processing means performs enhancement processing using
15 the enhancement function F7, in which the enhancement amount has been adjusted by the enhancement amount adjustment function F6. The output processing means outputs an output signal based on the image signal and the difference signal.

The visual processing device according to attachment 39 is the
20 visual processing device according to attachment 38 in which the output processing means performs a summing process of taking the sum of the image signal and the enhanced difference signal.

With the visual processing device of this invention, the dynamic range compression function F8 is for example a direct proportion
25 function of a proportion coefficient 1.

The visual processing device according to attachment 40 is the visual processing device according to attachment 38 in which the output processing means includes DR compression means that performs dynamic range (DR) compression with respect to the image signal, and

performs a summing process of taking the sum of the DR compressed image signal and the enhanced difference signal.

With the visual processing device of this invention, the DR compression means uses the dynamic range compression function F8 to perform dynamic compression of the image signal.

The visual processing device according to attachment 41 comprises input signal processing means and signal computation means. The input signal processing means performs spatial processing of an image signal that has been received as input, and outputs a processed signal. The signal computation means outputs an output signal based on a computation that adds a value obtained by correcting the gradation of the image signal to the value obtained by enhancing the difference between the image signal and the processed signal.

With the visual processing device of this invention, the difference between the image signal and the processed signal expresses the sharp component of the image signal. Also, enhancement of the sharp component and gradation correction of the image signal are performed independently. Thus, it is possible to perform a constant enhancement of the sharp component regardless of the gradation correction amount of the image signal.

The visual processing device according to attachment 42 is the visual processing device according to attachment 41 in which the signal computation means computes a value C of the output signal with respect to a value A of the input signal, a value B of the processed signal, an enhancement function F11, and a gradation correction function F12, according to the equation $F12(A) + F11(A-B)$.

Here, the value C of the output signal shows the following. That is, the difference (A-B) between the value A of the image signal and the value B of the processed signal expresses the sharp signal, for example.

Also, F11(A-B) for example expresses the enhancement processing of the sharp signal. It also indicates that the gradation-corrected image signal and the enhanced sharp signal have been added.

5 With the visual processing device of this invention, it is possible to perform a fixed contrast enhancement regardless of the gradation correction.

The visual processing device according to attachment 43 is the visual processing device according to attachment 42 in which the signal computation means has enhancement processing means and summing
10 means. The enhancement processing means performs enhancement processing of a difference signal of the difference between the image signal and the processed signal. The summing means takes the sum of the gradation-corrected image signal and the enhanced difference signal and outputs the result as an output signal.

15 With the visual processing device of this invention, the enhancement processing means performs enhancement processing of the difference signal using the enhancement function F11. The summing means uses the gradation correction function F12 to take the sum of the gradation-processed image signal and the enhanced difference signal.

20 The visual processing method according to attachment 44 comprises a first transformation step, a signal computation step, and a second transformation step. The first transformation step is step of transforming an input image data of a first predetermined range to a second predetermined range, and taking this as an image signal. The
25 signal computation step is a step of outputting an output signal of a third predetermined range based on a computation that includes at least one of a computation for compressing the dynamic range of the image signal, and a computation for enhancing a ratio between the image signal and a processed signal that is obtained by spatially processing the

image signal. The second transformation step is a step of transforming the output signal of the third predetermined range to a fourth predetermined range, and taking this as output image data. The second predetermined range is determined based on a target contrast value, which is a target value of the contrast when the image is displayed. The third predetermined range is determined based on an actual contrast value, which is a contrast value in the display environment when the image is displayed.

With the visual processing method of this invention, it is for example possible to compress the dynamic range of the overall image down to the actual contrast value that has dropped due to the presence of ambient light, while locally maintaining the target contrast value. Thus, the image after visual processing has an improved visual effect.

The visual processing device according to attachment 45 comprises first transformation means, signal computation means, and second transformation means. The first transformation means transforms input image data of a first predetermined range to a second predetermined range, and takes this as an image signal. The signal computation means outputs an output signal of a third predetermined range based on a computation that includes at least one of a computation for compressing the dynamic range of the image signal, and a computation for enhancing a ratio between the image signal and a processed signal that is obtained by spatially processing the image signal. The second transformation means transforms the output signal of the third predetermined range to a fourth predetermined range, and takes this as output image data. The second predetermined range is determined based on a target contrast value, which is a target value of the contrast when the image is displayed. The third predetermined range is determined based on an actual contrast value, which is a

contrast value in the display environment when the image is displayed.

With the visual processing device of this invention, it is for example possible to compress the dynamic range of the overall image down to the actual contrast value that has dropped due to the presence
5 of ambient light, while locally maintaining the target contrast value. Thus, the image after visual processing has an improved visual effect.

The visual processing program according to attachment 46 is a visual processing program for causing a computer to perform visual processing, the visual processing program causing the computer to
10 perform a visual processing method that comprises a first transformation step, a signal computation step, and a second transformation step.

The first transformation step is a step of transforming an input image data of a first predetermined range to a second predetermined range, and taking this as an image signal. The signal computation step
15 is a step of outputting an output signal of a third predetermined range based on a computation that includes at least one of a computation for compressing the dynamic range of the image signal, and a computation for enhancing a ratio between the image signal and a processed signal that is obtained by spatially processing the image signal. The second
20 transformation step is a step of transforming the output signal of the third predetermined range to a fourth predetermined range, and taking this as output image data. The second predetermined range is determined based on a target contrast value, which is a target value of the contrast when the image is displayed. The third predetermined
25 range is determined based on an actual contrast value, which is a contrast value in the display environment when the image is displayed.

With the visual processing program of this invention, it is for example possible to compress the dynamic range of the overall image down to the actual contrast value that has dropped due to the presence

of ambient light, while locally maintaining the target contrast value. Thus, the image after visual processing has an improved visual effect.

With the visual processing device of the present invention, it is possible to obtain an image that has a better visual effect for the user
5 who will view the visually processed image, and this device can be favorably employed as a visual processing device, and in particular, as a visual processing device that performs visual processing such as spatial processing or gradation processing of an image signal.
